AMERICAN MUSEUM OF NATURAL HISTORY, NEW YORK, N.Y.

INDEX TO VOLUME 90, 1981

AUTHORS AND TITLES

A

Alamuddin, N.S., *Marriage—Lebanese Style*, Apr., p. 8
Alcock, J., *Seduction on the Wing*, Dec., p. 36
Alison, R.M., *The Earliest Traces of a Conservation Conscience*, May, p. 72
Allaway, J., *The African Elephant's Drinking Problem*, Apr., p. 30
Archibald, G., *Last Call for the Siberian Crane*, Mar., p. 58
Arnold, R.M., *Weeds That Ride the Rails*, Aug., p. 58
Avise, J.C., *A Matter of Lights and Death*, Sept., p. 6

B

Bancaud, H., *The Acadians of Belle-Ile-en-Mer*, Jan., p. 48
Billings, W.D., *Plants in High Places*, Oct., p. 82
Bitterbaum, E.J., *A Martin House Is Not a Home*, May, p. 64
Boccaccio, A., *Street Urchins of Colombia*, Apr., p. 40
Boltin, L., *British Museum (Natural History)*, Jan., p. 38
Bond, J.M., Jr., *Review*, Oct., p. 118
Brown, C.R., *A Martin House Is Not a Home*, May, p. 64
Brownlee, D.E., *Cosmic Dust*, Apr., p. 73
Bruemmer, F., *Eskimos Are Warm People*, Oct., p. 42
Bryant, J.P., *Hare Trigger*, Nov., p. 46
Byers, J.A., *Peaceable Peccaries*, June, p. 60

C

Campbell, T.C., *More Is Not Necessarily Better*, May, p. 12
Capriotti, E.R., *Seyfert Galaxies*, Feb., p. 82
Carey, C., *Shivering Finches*, Oct., p. 58
Carpenter, G., *The Importance of Mother's Milk*, Aug., p. 6
Cartmill, M., *Review*, Apr., p. 90; Dec., p. 82
Christopher, T.A., *The Seeds of Botany*, Mar., p. 50
Christy, J.W., *Searching for Dim Companions*, June, p. 70
Coffey, M., *In Praise of Plains*, Nov., p. 54
Cook, R.E., *Toxic Tailings and Tolerant Grass*, Mar., p. 28; *Disturbing Plants*, Apr., p. 22; *Plant Parenthood*, July, p. 30; *Pin Cherry Perceptions*, Nov., p. 96
Crawford, R.L., *A Matter of Lights and Death*, Sept., p. 6

D

Delcourt, H.R., *The Virtue of Forests, Virgin and Otherwise*, June, p. 32
del Moral, R., *Life Returns to Mount St. Helens*, May, p. 36
Deyrup, M., *Deadwood Decomposers*, Mar., p. 84

E

Echevarri, J., *Bees for the Birds*, Apr., p. 36
Eldredge, N., *The Elusive Eureka*, Aug., p. 24

F

Felsman, K., *Street Urchins of Colombia*, Apr., p. 40
Foott, J., *Yellowstone Buffalo Winter*, Dec., p. 58
Furst, P.T., *Review*, Jan., p. 92

G

Geist, V., *Neanderthal the Hunter*, Jan., p. 26; *Review*, July, p. 86
Gerlach, L.P., *The Ecology Movement After Ten Years*, Jan., p. 12
Godfrey, L.R., *The Flood of Anti-evolutionism*, June, p. 4
González Grande, J.L., *Spain's Imperial Eagle*, June, p. 40
Gould, S.J., *The Politics of Census*, Jan., p. 20; *Hyena Myths and Realities*, Feb., p. 16; *Kingdoms Without Wheels*, Mar., p. 42; *A Most Chilling Statement*, Apr., p. 14; *The Titular Bishop of Titiopolis*, May, p. 20; *Piltdown in Letters*, June, p. 12; *What, if Anything, Is a Zebra?* July, p. 6; *What Color Is a Zebra?* Aug., p. 16; *Quaggas, Coiled Oysters, and Flimsy Facts*, Sept., p. 16; *Review*, Sept., p. 92; *A Visit to Dayton*, Oct., p. 8; *The Ultimate Parasite*, Nov., p. 7; *Agassiz in the Galâpagos*, Dec., p. 7
Greenough, J.W., *Whales at Table*, Dec., p. 30
Griffiths, N.E.S., *The Acadians of Belle-Ile-en-Mer*, Jan., p. 48
Grobecker, D.B., *Steady as a Rock, Fast as Lightning*, May, p. 50
Grosser, M., *Genesis of the* Gossamer Condor, Mar., p. 64
Grossman, L., *Telltale Inclusions*, Apr., p. 68
Gwaltney, J.L., *Heirs of Disaster*, Mar., p. 12

H

Hansen, J.V.E., *Clothing for Cold Climes*, Oct., p. 90
Harrison, R.E., *Review*, Aug., p. 78
Hendrey, G.R., *Acid Rain and Gray Snow*, Feb., p. 58
Heschong, L., *Thermal Necessity*, Oct., p. 32
High, C., *Indoor Air Pollution*, Oct., p. 110
Huntington, G.E., *Children of the Hutterites*, Feb., p. 34
Hutchins, M., *Olympic Mountain Goats*, Jan., p. 58

I

Ingersoll, A.P., *Saturn's Surprises*, Sept., p. 44

J

Johnson, J., *Leave It to Beaver*, July, p. 44

K

Kastner, J., *Review*, May, p. 88
Kelsall, J.P., *Review*, Nov., p. 110
Kessler, E., *House Warming*, Oct., p. 104
Knutson, R.M., *Flowers That Make Heat While the Sun Shines*, Oct., p. 75
Kugelmass, J.M., *I'd Rather Be a Messenger*, Aug., p. 66

L

Lepp, G.D., *A Least Tern Makes a Right Turn*, Nov., p. 62
Love, M., *With a Little Help from My Friends*, Nov., p. 16

M

Maran, S., *The Solar Shrink*, Jan., p. 82; *A Near Miss*, Mar., p. 98; *A Nonconforming Supernova*, May, p. 78; *Seeing Double and Seeing Triple*, July, p. 24; *Debut of an Interstellar Bubble*, Aug., p. 28; *Getting Ready for Halley*, Nov., p. 32; *Stellar Togetherness*, Dec., p. 24
Marsh, R.L., *Shivering Finches*, Oct., p. 58
Martin, W.K., *Protean Beauty*, Dec., p. 42
Mason, B., *A Lode of Meteorites*, Apr., p. 62
Massey, B.W., *A Least Tern Makes a Right Turn*, Nov., p. 62
Mathewson, M.T., and W., *Early Bird Photographers*, Dec., p. 16
Milliman, J.D., *A Voyage in the East China Sea*, Jan., p. 70
Mitchell, E., *The Whale Behind the Tusk*, Aug., p. 50
Mulcahy, D.L., *Rise of the Angiosperms*, Sept., p. 30

N

Nicholson, T.D., *Celestial Events*, Jan., p. 84; Feb., p. 91; Mar., p. 104; Apr., p. 86; May, p. 70; June, p. 74; July, p. 90; Aug., p. 76; Sept., p. 82; Oct., p. 126; Nov., p. 40; Dec., p. 80
Nietschmann, B., and J., *Good Dugong, Bad Dugong; Bad Turtle, Good Turtle*, May, p. 54
Nylander, J.C., *Come, Gather Round the Chimney*, Oct., p. 98

O

Olano, M., *Bees for the Birds*, Apr., p. 36
Ott, E.A., *Vermont Country Calendar*, Mar., p. 72

P

Perlès, C., *Hearth and Home in the Old Stone Age*, Oct., p. 38
Price, R., and S., *Art of the Rain Forest*, Sept., p. 54

R

Radcliffe, B., *The Ecology Movement After Ten Years*, Jan., p. 12
Raven, P.H., *Tropical Rain Forests: A Global Responsibility*, Feb., p. 28
Reaka, M.L., *The Hole Shrimp Story*, July, p. 36
Reeves, R.R., *The Whale Behind the Tusk*, Aug., p. 50
Reiter, E.R., *The Tibet Connection*, Sept., p. 64
Rensberger, B., *Review*, June, p. 76
Rogers, L., *A Bear in Its Lair*, Oct., p. 64
Rozin, E., and P., *Culinary Themes and Variations*, Feb., p. 6

S

Scheffer, V.B., *Review*, Feb., p. 94
Schildkrout, E., *Young Traders of Northern Nigeria*, June, p. 44
Schoenbaum, S., *Shakespeare—The Poet's Worlds*, June, p. 54
Sheets, P.D., *Volcanoes and the Maya*, Aug., p. 32
Sokolov, R., *The Taming of the Grain*, Jan., p. 98; *Forbidding Fruit*, Feb., p. 102; *Blueberry Blues*, Mar., p. 116; *Chili con Blarney*, Apr., p. 96; *Olympic Trials*, May, p. 92; *The Lime That Failed*, June, p. 88; *A Fish Story*, July, p. 100; *Planter's Lunch*, Aug., p. 88; *Roots*, Sept., p. 98; *Sunbelt Cuisine*, Oct., p. 135; *Cut and Dried*, Nov., p. 116; *Endangered Pisces*, Dec., p. 92
Sordahl, T.A., *Sleight of Wing*, Aug., p. 42
Starin, E.D., *Monkey Moves*, Sept., p. 36
Starr, P.D., *Marriage—Lebanese Style*, Apr., p. 8
Stevens, V., *Olympic Mountain Goats*, Jan., p. 58
Stinchecum, A.M., *Enduring Cold the Japanese Way*, Oct., p. 50
Strickland, D., *The Eskimo vs. the Walrus vs. the Government*, Feb., p. 48
Swanton, H., *Ralph Hoffmann: Unsung Guide to the Birds*, Nov., p. 20
Swinton, W.E., *British Museum (Natural History)*, Jan., p. 38

T

Tattersall, I., *Review*, Mar., p. 92
Turnbull, C., *East African Safari*, May, p. 26; *A Pilgrimage in India*, July, p. 14; *Holy Places and People of India*, Sept., p. 76

V

Vuilleumier, F., *The Origin of High Andean Birds*, July, p. 50

W

Waldheim, K., *On Asian Peoples*, Jan., p. 86
Webbon, B., *Survival in Space*, Dec., p. 50
Weitz, C.A., *Weathering Heights*, Nov., p. 72
West, T.L., *Llama Caravans of the Andes*, Dec., p. 62
Winick, M., *Food and the Fetus*, Jan., p. 76
Wood, J.A., *Long-playing Records*, Apr., p. 56

Z

Zimen, E., *Italian Wolves*, Feb., p. 66

SUBJECT MATTER

Acadians, Canada, Jan., p. 48
Acidification, Feb., p. 58
AFRICA
East, safari, May, p. 26
Elephants, Apr., p. 30
Northern Nigeria, June, p. 44
Red colobus monkeys, Sept., p. 36
Agassiz, Dec., p. 7
ALASKA
Eskimos, Feb., p. 48; Oct., p. 42
Whales, Dec., p. 30
Allende meteorite, Apr., p. 68
Andean highlands, llama caravans, Dec., p. 62
Angiosperms, Sept., p. 30
Anglerfish, May, p. 50
Antarctica and meteorites, Apr., p. 62
ANTHROPOLOGY
Acadians, Jan., p. 48
Andes, llama caravans, Dec., p. 62
City life, New York, Aug., p. 66
Colombia, Apr., p. 40
Druse sect, Apr., p. 8
Eskimos, Feb., p. 48; Oct., p. 42
Hausa society, June, p. 44
Hutterites, Feb., p. 34
Japanese, Oct., p. 50
Maroon tribes, Sept., p. 54
Maya, Aug., p. 32
Mexican village, Mar., p. 12
Neanderthal man, Jan., p. 26
Quechuas, Nov., p. 72
Sherpas, Nov., p. 72
Torres Strait Islanders, May, p. 54
Vermont, Mar., p. 72
Antievolutionism, June, p. 4
Archeology, Maya, August, p. 32; Piltdown man, June, p. 12
ART
Maroon tribes, Suriname, Sept., p. 54
Asteroids, Apr., p. 72
ASTRONOMY
Celestial Events, Jan., p. 84; Feb., p. 91; Mar., p. 104; Apr., p. 86; May, p. 70; June, p. 74; July, p. 90; Aug., p. 76; Sept., p. 82; Oct.,

p. 126; Nov., p. 40; Dec., p. 80
Comet, Halley's, Nov., p. 32
Cosmic dust, Apr., p. 72
Double-star systems, June, p. 70
Galaxies, Feb., p. 82
Meteorites, Apr., p. 52; p. 58; p. 62; p. 68; p. 78
Moon, Apr., p. 58
Nebula, Aug., p. 28
Quasars, July, p. 24
Saturn, Sept., p. 44
Seyfert Galaxies, Feb., p. 82
Sky Reporter, Jan., p. 82; Feb., p. 82; Mar., p. 98; May. p. 78; June, p. 70; July, p. 24; Aug., p. 28; Nov., p. 32; Dec., p. 24
Stars, binary, Dec., p. 24
Sun, Jan., p. 82
Supernova, May, p. 78
AT THE AMERICAN MUSEUM
Asian people, Jan., p. 86
Bark cloth, Nov., p. 104
Exhibition Hall artists, Aug., p. 84
Expeditions, Mar., p. 108
Film festival, Oct., p. 128
Frozen fish, May, p. 84
Hall of Meteorites, Apr., p. 52
Life casts, June, p. 84
Mastodon, Sept., p. 72
Meteorites, Apr., p. 78
Microscopes, Feb., p. 98
Past and future of, July, p. 92
Australia, May, p. 54
Avian migration, Sept., p. 6
Aviation, *Gossamer Condor,* Mar., p. 64
Avocet, American, Aug., p. 42
Baffin Islands, Aug., p. 50
Bears, Oct., p. 64
Beaver, July, p. 44
Bees, Apr., p. 64
Bicycle messengers, New York, Aug., p. 66
Binary stars, Dec., p. 24
BIOLOGY
Fetus, Jan., p. 76
Human milk, Aug., p. 6
BIOS
Grass, species of, Mar., p. 28
Pin cherry, Nov., p. 96
Plants, Mar., p. 28; Apr., p. 22; July, p. 30
BIRDS
American avocet, Aug., p. 42
Andean, July, p. 50
Avian migration, Sept., p. 6
Eagle, June, p. 40
European bee eater, Apr., p. 36
Finches, Oct., p. 58
Guide to, Nov., p. 20
Martins, purple, May, p. 64
Photographers of, Dec., p. 16
Siberian cranes, Mar., p. 58
Stilts, Aug., p. 42
Terns, Nov., p. 62
Bird watching, Nov., p. 20
Blueberries, Mar., p. 116
Botanical garden, Padua, Italy, Mar., p. 50
BOTANY
Douglas fir trees, Mar., p. 84
Forests, June, p. 32
Grass, Mar., p. 28
Herbs, Feb., p. 6
Lime, June, p. 88
Persimmon, Feb., p. 102
Pin cherry, Nov., p. 96
Plants
Alpine, Oct., p. 82
Alterations of, Apr., p. 14
Communities, Apr., p. 22
Flowering, July, p. 30; Sept., p. 30; Oct., p. 75
Research, Mar., p. 50
and Toxins, Nov., p. 46
Weeds, Aug., p. 58
Proteacea, Dec., p. 42
Rain forests, Feb., p. 28; Sept., p. 54
Sassafras trees, Sept., p. 98
British Museum (Natural History), Jan., p. 38
Buffalo, Dec., p. 58
Camels, Mar., p. 42; July, p. 86
CANADA
Acadians, Jan., p. 48
Hutterites, Feb., p. 34
Celestial Events *see* Astronomy
Census, Jan., p. 20
Chili, Apr., p. 96
Chimney, Oct., p. 98
China, coastal occanography, Jan., p. 70
CLIMATE
Changes, Sept., p. 64
Great Plains, Nov., p. 54
Keeping warm, Oct., p. 32; p. 38; p. 42; p. 50; p. 58; p. 64; p. 75; p. 82; p. 90; p. 98; p. 104; p. 110
Mountain altitude, Nov., p. 72
and Neanderthal man, Jan., p. 26
Rain and snow, Feb., p. 58
Colombia, Apr., p. 40
Comets, Apr., p. 72; Nov., p. 32
CONSERVATION
Ancient concept, May, p. 72
Birds, Dec., p. 16
Terns, Nov., p. 62
Cosmic dust, Apr., p. 72
Cranes, Siberian, Mar., p. 58
DNA, Nov., p. 7
Double-star system, June, p. 70
Douglas fir trees, Mar., p. 84
Druse, Apr., p. 8
Eagles, June, p. 40
East China Sea, Jan., p. 70
ECOLOGY
Forest, Mar., p. 84
Toxins, function of, Nov., p. 46
Ecosystem, Mar., p. 84; June, p. 32
Elephants, African, Apr., p. 30
ENDANGERED SPECIES
Siberian cranes, March, p. 58
Spanish imperial eagle, June, p. 40
Terns, Nov., p. 62
ENVIRONMENT
Ecology movement, Jan., p. 12
High altitude, Nov., p. 72
Mount St. Helens, May, p. 36
Vermont, Mar., p. 72
Eskimos, Feb., p. 48; Oct., p. 42
European bee eater, Apr., p. 36
EVOLUTION
Anti-, June, p. 4
Grass, Mar., p. 28
Insect mating systems, Dec., p. 36
Mammals, Mar., p. 42
Fetus, Jan., p. 76
Fibers, natural and synthetic, Oct., p. 90
Finches, Oct., p. 58
Fireplace, Oct., p. 104; and pollution, Oct., p. 110
FISHES
Anglerfish, May, p. 50
Salmon, July, p. 100
Whitefish, Dec., p. 92
Flight, human-powered, Mar., p. 64
FOOD
Blueberries, Mar., p. 116
Chili, Apr., p. 96
and fetus, Jan., p. 76
Herbs, Feb., p. 6
Lime, June, p. 88
Meat, Nov., p. 116
Olympia oyster, May, p. 92
Persimmon, Feb., p. 102
Salmon, July, p. 100
Sassafras, Sept., p. 98
Southern cooking, Aug., p. 88; Oct., p. 135
Whitefish, Dec., p. 92
Wild rice, Jan., p. 98
FOREST
Ecosystem, Mar., p. 84
Rain forest, Feb., p. 28; Sept., p. 54
Fossil, Aug., p. 24; April, p. 90
Franklin stove, Oct., p. 32
FRUIT
Blueberries, Mar., p. 116
Lime, June, p. 88
Persimmon, Feb., p. 102
Galápagos, Dec., p. 7
Galaxies, Seyfert, Feb., p. 82
Genes, Nov., p. 7
Geology, volcanoes, May, p. 36; Aug., p. 32
Goats, mountain, Jan., p. 58
Great Plains, Nov., p. 54
Halley's comet, Nov., p. 32
Hare, snowshoe, Nov., p. 46
Hausa society, June, p. 44
Herbs, Feb., p. 6
HISTORY
of Earth, Apr., p. 58
of science, May, p. 20; Sept., p. 16
Human milk, Aug., p. 6
HUMAN STRATEGY
Druse sect, Apr., p. 8
Mexican village, Mar., p. 12
Hutterites, child rearing, Feb., p. 34
Hyenas, Feb., p. 16
Ichthyology, May, p. 84
India, July, p. 14; Sept., p. 76
INSECTS
Bees, Apr., p. 36
and Douglas fir trees, Mar., p. 84
Wasps, Dec., p. 36
Insulation of houses, Oct., p. 104
INVERTEBRATES
Fossil, Aug., p. 24
Shrimp, July, p. 36
ITALY
Padua, Mar., p. 50
Wolves, Feb., p. 66
Japan, Oct., p. 50
Jerky, Nov., p. 116
KEEPING WARM
Alpine plants, Oct., p. 82
Birds, Oct., p. 58

Eskimos, Oct., p. 42
Fibers, Oct., p. 90
Franklin stove, Oct., p. 32
Indoors and pollution, Oct., p. 110
Insulation, Oct., p. 104
Japanese, Oct., p. 50
Mammals, Oct., p. 64
New England and chimneys, Oct., p. 98
North American Arctic, Oct., p. 42
Plants, Oct., p. 75
and the Stone Age, Oct., p. 38
Lebanon, Druse sect, Apr., p. 8
Lime, June, p. 88
Llama caravans, Dec., p. 62
London, natural history museum, Jan., p. 38
MAMMALS
Bears, Oct., p. 64
Beavers, July, p. 44
Buffaloes, Dec., p. 58
Camels, Mar., p. 42
Dugongs, May, p. 54
Elephants, Apr., p. 30
Goats, Jan., p. 58
Hyenas, Feb., p. 16
Llamas, Dec., p. 62
Monkeys, Sept., p. 36
Peccaries, June, p. 60
Snowshoe hares, Nov., p. 46
Walrus, Feb., p. 48
Whales, Aug., p. 50; Dec., p. 30
Wolves, Feb., p. 66
Zebras, July, p. 6; Aug., p. 16
Mantis shrimp, July, p. 36
Maroon tribes, Sept., p. 54
Martins, purple, May, p. 64
MATTER OF TASTE
Blueberries, Mar., p. 116
Chili, Apr., p. 96
Fish, July, p. 100
Lime, June, p. 88
Meat, jerked, Nov., p. 116
Oysters, May, p. 92
Persimmon, Feb., p. 102
Sassafras, Sept., p. 98
Southern cooking, Aug., p. 88; Oct., p. 135
Whitefish, Dec., p. 92
Wild rice, Jan., p. 98
Maya, Aug., p. 32
Meat, dried, Nov., p. 116
Messengers, Aug., p. 66
Meteorites, Apr., p. 52; p. 56; p. 62; p. 68; p. 78
Meteoroid, Mar., p. 98
MEXICO
Meteorite, Apr., p. 68
Village people, Mar., p. 12
Milk, human, Aug., p. 6
Monkey trial, Oct., p. 8
Monkeys, red colobus, Sept., p. 36
Moon, Apr., p. 58
Mount St. Helens, May, p. 36
Narwhals, Aug., p. 50
NASA, Dec., p. 50
National park, Olympic mountain, Jan., p. 58
NATURALIST AT LARGE
Environment, Nov., p. 16
Fossil, Aug., p. 24
Neanderthal man, Jan., p. 26
Rain forests, Feb., p. 28
Neanderthal man, Jan., p. 26
Nebula, emission, Aug., p. 28
North American Arctic and keeping warm, Oct., p. 42
Nutrition and fetus, Jan., p. 76
Nutritional biochemistry, May, p. 12
Oceanography, Chinese, Jan., p. 70
Oysters, May, p. 92
Padua, botanical garden, Mar., p. 50
Peccaries, collared, June, p. 60
Pediatrics, Jan., p. 76
Persimmon, Feb., p. 102
Photographic competition, winners, July, p. 66

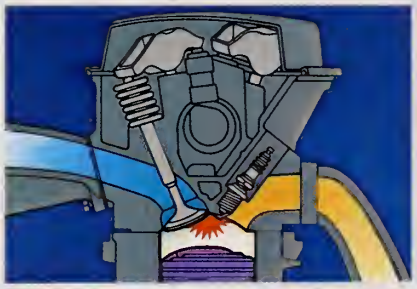
FORD ESCORT BUILT TO TAKE ON THE WORLD... AND DOING IT.

ENGINEERING TEAMS FROM AMERICA AND OVERSEAS JOIN FORCES TO CREATE A NEW CAR WITH BETTER IDEAS FROM AROUND THE WORLD

Top engineers drawn from the worldwide resources of Ford Motor Company teamed up to create Escort. They pooled their expertise...compared, tested, evaluated, experimented—to come up with better ideas.

The result: a high-mileage car built in America to take on the world. Escort will be made in America for American drivers...with other models built and sold overseas.

HIGH MILEAGE THROUGH ADVANCED TECHNOLOGY



Escort has higher gas mileage ratings than subcompacts such as VW Rabbit, Honda Accord, Toyota Corolla hatchback—yet Escort has more room—in fact, Escort has the room of a compact (based on EPA Volume Index).

30 EPA EST MPG* **44** EST HWY*

*Applicable only to sedans without power steering or A/C. For comparison. Your mileage may differ depending on speed, distance, weather. Actual hwy mileage and Calif. ratings lower. Excludes diesels.

ONE OF THE MOST POWER-EFFICIENT ENGINES AVAILABLE IN AMERICA

Escort's new-design compound valve hemispherical head (CVH)

engine gives you high mileage plus power for freeway driving.

FRONT-WHEEL DRIVE AND FOUR-WHEEL INDEPENDENT SUSPENSION

Escort comes with front-wheel drive...four-wheel fully independent suspension...rack-and-pinion steering...stabilizer bar...new all-season steel-belted radials, and other road-control features.

DRIVE A WORLD CAR

Whether you buy or lease, see your Ford Dealer now to order your Escort...3-door Hatchback, 4-door Liftgate...or even a Squire wagon option. And remember to ask about Ford's Extended Service Plan.

Escort Liftgate...4-doors and wagon room when you need it.

The Heritage Club Presents...

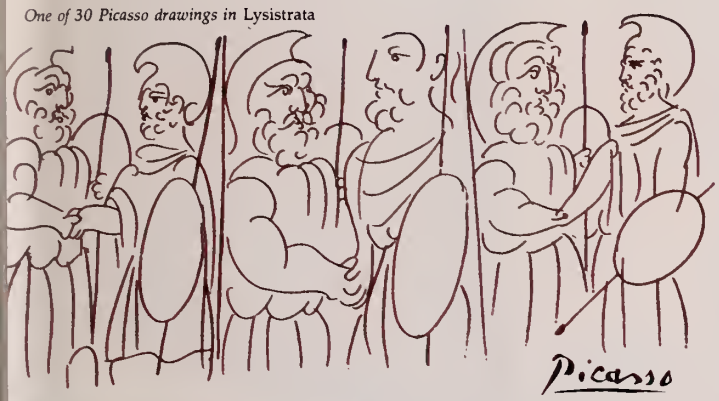
Five Ways to Recognize the Outstanding Value of Heritage Club Fine Books

Heirloom editions of the classics at only $12.00 each.

For more than 40 years, book lovers have turned to The Heritage Club because it offers a combination of advantages unmatched by any other classics library...and at an outstanding value.

1 Important Books of Exceptional Beauty and Elegance—Each a Work of Art and a Great Work of Literature.

Throughout the world, Heritage Club books have come to be regarded as definitive editions of the world's greatest classics. The reason is that they are not only masterpieces of literature, but masterpieces of the book crafting art as well.



Over the years, The Heritage Club has orchestrated the talents of the world's most renowned artists, typographers, designers, binders and printers to produce books which rank among the finest and most beautiful in the world. Indeed, Heritage books have repeatedly captured top design awards and honors in Europe, Canada and the United States. They have even been exhibited at the Metropolitan Museum of Art.

Every volume evidences this great tradition. The bindings, for example, display a wide variety of colors and rich fabrics. The elegant chapter headings... the hand-set typefaces...even the tone and finish of the paper are selected to suit the meaning and mood of each classic.

When you display such books on your shelves, you will enjoy deep feelings of pride. For these are fine books without compromise. Together, they form a beautiful and harmonious library that lends color, taste and dignity to your home.

2 Original Art Created Exclusively for Heritage Editions by the World's Greatest Artists...Picasso, Rockwell, Grant Wood and others.

One of 30 Picasso drawings in Lysistrata

Norman Rockwell's Tom Sawyer

Sherlock Holmes as seen by Frederic Dorr Steele

To add an enchanting visual dimension to the world's greatest books, The Heritage Club has, over the years, commissioned leading figures in the arts to illustrate each volume. Hence, Heritage editions abound with magnificent original works—many in full color—etchings, wood engravings, drawings, lithographs, and paintings—all designed to increase the pleasure you and your family derive from each book.

It is a sheer delight, for example, while reading the immortal Greek comedy, *Lysistrata*, to see the beautiful young women and courageous warriors of ancient Athens through the eyes of Pablo Picasso. The original works he created expressly for this book now hang in the Museum of Modern Art. Today, the only way you can own these drawings is to possess The Heritage Club edition!

To illustrate *The Adventures of Tom Sawyer* and *Huckleberry Finn*, The Heritage Club, in 1936, commissioned exclusive works by Norman Rockwell. For who better than the warm and witty Rockwell could capture the mischief of Tom and Huck in their meanderings along Twain's beloved Mississippi River. And where else but in The Heritage Club could you find, in one volume, the words of America's most popular author enhanced by the art of America's best loved artist!

And so it goes throughout the collection...Grant Wood's striking paintings for *Main Street* give an extra depth to Sinclair Lewis' memorable characters. The drawings in the Heritage edition of *The Adventures of Sherlock Holmes* were done by Frederic Dorr Steele, the famous illustrator of the original Holmes serialization.

Grant Wood illustration from Main Street

If any publisher, including ourselves, tried to create such a magnificent classics library today, it would be utterly impossible at this price. We can do so only because we long ago acquired the rights to the priceless art of Picasso, Rockwell and others, before the peak of their fame—before the cost of such originals put them beyond the reach of almost all book publishers.

3 Exclusive Introductions by the Twentieth Century's Leading Literary Figures.

A. A. Milne

Sinclair Lewis

Thornton Wilder

Theodore Dreiser

For more than four decades, Heritage has also engaged the leading scholars and critics of our time to write introductions to every Heritage book. Giants of the literary world such as Sinclair Lewis, Thornton Wilder, A.A. Milne, Clifton Fadiman, Theodore Dreiser and others will give you priceless insights into each author's life and times, and the literary treasures a careful reader can unearth if he knows where to look. These masterful essays give you a heightened appreciation of each great book.

(continued on next page)

(continued from previous page)

4 Heritage Club Books are Among the Best Made Books in the World.

Like the classics themselves, Heritage Club books will endure for generations. Compare a Heritage edition to the usual book on your shelf and you will be astonished by the obvious differences.

You will note, for example, the covers are thick and sturdy. They won't curl or warp as do those of ordinary books. The cover fabrics are specially suited to resist moisture and ageing.

The papers are exceptionally heavy and meant to last 100 years without cracking or turning yellow.

In binding, the pages are meticulously thread-sewn. Then, each book is reinforced to afford a double measure of strength and durability.

As a final assurance of excellence and quality, every Heritage book is thoroughly inspected for even the slightest flaw. It must be perfect in every detail before it can be released to a Heritage Club member.

Sturdy lifetime slipcase accompanies each book and protects against sunlight and dust

Elegant readable type faces individually selected for each volume

All originally typeset by hand for sharpest image

Flawless full-color reproductions of original works of art

Heavyweight 88 point cover board resists curling with age

Traditional decorative headband—a hallmark of fine books

Pages thread-sewn for extra strength in binding

Highest-quality, acid-neutral paper won't turn yellow

Covers of colorful, expensive, durable fabrics

5 Heritage Club Books Come with the Many Extra Benefits of Club Membership...All for Only $12 a Book.

Just as Heritage books stand head and shoulders above the ordinary, you will also find that Club Membership is a refreshing alternative to the way other book clubs operate. Here's how:

As a member, you will be spared the petty inconvenience of sending monthly notification each time you don't want a certain selection. Rather, you will receive, upon joining, a Prospectus of the Club's upcoming titles. You can freely choose only those you want to receive, which will then be sent at the rate of one per month. You, of course, may return any book within 30 days for a full refund, and you are at liberty to cancel your membership at any time.

You will also enjoy several delightful "extras"...

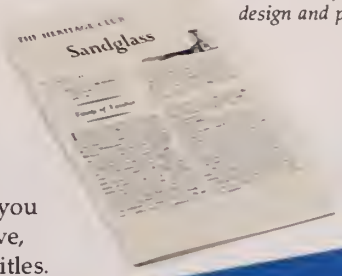
You'll receive a bonus book just for joining.

Because of the astonishing quality of our books, the Club would like to place in your hands, free of charge, a superb Heritage edition for your examination. This bonus volume will speak far more persuasively than any magazine announcement can about the beauty and elegance of Heritage books. If for any reason you are not satisfied, simply return it. Your membership will be cancelled and you will owe nothing. If you are delighted with your bonus book, you may then receive other volumes for just $12 each.

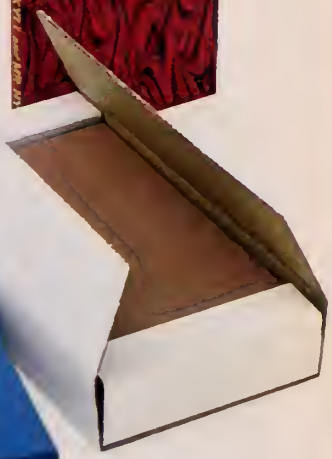
A copy of *The Sandglass*, the Club's own book guide, accompanies each edition, providing fascinating background information on the book, author, designer, artist, printer and others who helped make it a distinguished heirloom edition.

The Heritage Club's toll-free phone number lets you have any question or problem about membership handled quickly and personally.

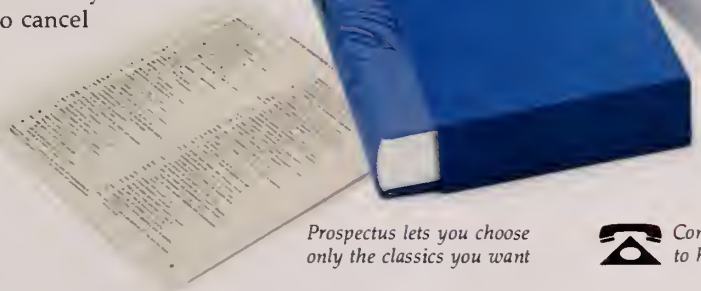
Since nothing is more disappointing than a damaged book, even our packaging is special. Doubly-reinforced shipping cartons, designed for each book, assure that your books will arrive in mint condition.



Prompt Action Required



To accept this invitation, you need only complete the Membership Application and return it promptly. Since the Club must plan printings in advance, you must act now if you are to take advantage of this bonus book offer and begin acquiring your own library of the world's greatest books in lasting heirloom editions.



Bonus book just for joining

The Sandglass *guide certifies the "pedigree" of each volume with details of its unique design and production*

Extra heavy packaging assures delivery in perfect condition

Prospectus lets you choose only the classics you want

Convenient toll-free phone number to handle any question or problem

129

Membership Application

THE HERITAGE CLUB
47 Richards Avenue
Norwalk, Conn. 06857

No payment required
Simply mail this application.

YES! I want to join The Heritage Club and begin building my own personal library of the greatest books of all time.

Send me my FREE first volume. Assuming this book is satisfactory, I will then send $12.00 (plus shipping and handling) to pay for the next volume in my Heritage library. I will continue to receive one volume per month in this manner for as long as I continue my membership.

I may cancel my membership at any time. Moreover, I may return any book within 30 days for a full credit or refund. If the first volume does not meet with my approval, I will return it and owe you nothing, and my membership will automatically be cancelled.

Betty Radcliffe's first fieldwork on the study of social movements concerned protest activities against a proposed high-voltage power line in central Minnesota (see "The Great Energy Standoff," *Natural History*, January 1978). By means of interviews with protesters, affected residents, employees of the utilities seeking to build the power line, and public officials involved in selecting a site, Radcliffe "observed at first-hand the development of a major protest movement." This kind of research, she feels, is an "essential preliminary to the formulation of good questionnaires" and prepared her for her work on our 1980 version of "You and the Ecology Movement." A graduate of St. Cloud State University and a former teacher, Radcliffe has worked as Luther Gerlach's research assistant at the University of Minnesota for the past seven years.

Since 1970, when *Natural History* published its first questionnaire on "You and the Ecology Movement," coauthor **Luther P. Gerlach** has been following the development of the environmental movement. Through research, analysis, and interviews, he has also examined the recent growth of other social movements and the controversy over energy. The 1980 version of the ecology questionnaire, which appeared in the June issue of *Natural History*, and the final report in this issue, reflect his interest in how various social movements work to "challenge and change American culture." Gerlach, who received his Ph.D. from the University of London, is professor of anthropology at the University of Minnesota. He is now studying the role of churches in Minnesota in several social issues, chiefly resource development and control.

In 1924, shortly after receiving a Ph.D. in comparative anatomy and vertebrate paleontology from Glasgow University in Scotland, **William E. Swinton** accepted a job at the Natural History Museum in London. He remained there for thirty-seven years, away only during World War II when he served in the British Navy. As a principal scientific officer in the Department of Geology and Paleontology, Swinton helped build up the museum's vertebrate paleontological collections and created the museum's dinosaur galleries. In 1961 he moved to the Royal Ontario Museum in Toronto, where from 1963 to 1966 he served as director. Since 1966, Swinton has been a professor of zoology and the history of science at the University of Toronto. He is currently emeritus professor of the university's Massey College.

THE NIKON FE
A CAMERA TO STIR YOUR EMOTIONS

The automatic Nikon FE is the creative camera par excellence – the embodiment of Nikon sophistication.

Its precise meter system sets correct exposures with uncanny accuracy, automatically. Or, just turn a dial for complete manual control. Either way, the pictures are razor sharp...pure Nikon.

Offering combined capabilities found in no other automatic, it accepts Nikon's extraordinary lenses, accessories and a true 3.5 fps motor drive.

A modern 35mm classic, the Nikon FE is the finest compact automatic in its class. Priced to make it an irresistible value too! Why settle for anything less.

The 1981 Natural History Photographic Competition Is Open

The Grand Prize-winner this year will have a rare opportunity to photograph exotic wildlife with a close-up lens. And the winner may not even be a photographer. Let us explain about the special 1981 contest:

The Grand Prize will be an eleven-day trip, including airfare from New York and a berth on the yacht *Buccaneer*, to the Galápagos Islands. Many fearless creatures on those islands let photographers walk right up to them. The tour, sponsored by the American Museum of Natural History, will be led by two Museum scientists.

Seventeen cash prizes, totaling $3,500, will go to winners in seven categories, including a special new one, Historical Photographs. In this category, you need not be the original photographer, but you do have to own the picture and it should be more than fifty years old. So search your attic and old albums for prize-winning pictures that fit our three major categories.

The three major categories are Animals (including birds and bugs); Plants and Their Environment, and The Human Family. First prizes of $500 will be awarded in each.

In addition, Merit Awards of $250 each will go to the best entries in four categories: Photomicrography; A Sequence in Nature (up to five photographs); Historical Photographs; and Humor in Nature. Ten Honorable Mentions of $100 each will be selected from all entries.

The winning entries will be published in the July issue of *Natural History* and exhibited at the American Museum of Natural History.

THE RULES

1. The competition is open to everyone except employees of the American Museum and their kin.
2. Competitors may submit up to five previously unpublished entries (a sequence is considered a single entry).
3. The Museum acquires the right to publish, exhibit, and use for promotion the winning photographs. The Museum assumes no responsibility for other entries.
4. Entries may be transparencies or prints, either color or black and white, up to 8 by 10 inches. Each must bear the photographer's name and address. Entries must *not* be mounted in glass.
5. Enclose a self-addressed, stamped envelope for the return of entries.
6. Entries must be postmarked no later than April 1, 1981.

Pack them carefully and mail them to:

Natural History Photographic Competition
11 West 77th Street
New York, New York 10024

And good luck!

Born and raised in England, **Naomi E.S. Griffiths** began her studies of the Acadians when she arrived in Canada in 1956 to take a master's degree at the University of New Brunswick. Although she returned to England to earn her Ph.D. in history from London University, her professional career has been linked to Canada and the Acadians. Their resilience, despite a troubled history that includes a mass deportation in 1755, has fascinated Griffiths. She points out that, unlike many other peoples, the Acadians never believed they needed a separate state in order to preserve their identity. At present dean of the Faculty of Arts at Carleton University in Ottawa, Griffiths teaches Acadian and French history.

"My interest in biology developed quite early," writes **Michael Hutchins**. "As a child in rural Iowa I collected insects, amphibians, and reptiles and observed their habits. The crowning glories of these early explorations were the hatching of a luna moth from a cocoon and the raising of a pair of tiger salamanders." Now a doctoral candidate in psychology at the University of Washington, Hutchins's primary research is focused on the evolution of social behavior in birds and mammals. He is continuing his work on the behavioral ecology of mountain goats in Olympic National Park and is applying for a postdoctoral fellowship to study fratricide in the masked booby, a sea bird that nests on oceanic islands.

Also a doctoral candidate at the University of Washington, but in forestry (wildlife biology), coauthor **Victoria Stevens** is concentrating on the population biology of the introduced mountain goat population on the Olympic Peninsula. She has recorded the reproductive history of more than one hundred marked individuals and has done a comparison of the data for nine subpopulations of mountain goats, following their dispersal into new areas and observing their food customs and use of the habitat.

"Most satisfying," says **John D. Milliman** of his work in Chinese waters last summer. "I've long been interested in the big rivers of the world and you can't understand them unless you work in Asia." When that opportunity arose, he therefore jumped at it. An associate scientist at Woods Hole Oceanographic Institution, with degrees in geology and oceanography, Milliman was the U.S. project coordinator on the research voyage described in his article. As a self-confessed foodophile, he also enjoyed the traditional banquets, especially one in Shanghai the night before the cruise began. "It was a fantastic delight," he says. "Eighteen courses. But I must admit, I only got through twelve of them."

The 300,000 Mile Catalogue

From Willoughby & Taylor, Ltd.
International Merchants

300,000 miles. That is approximately how far one would have to travel to find the sources for all the merchandise in the new full-colour Willoughby & Taylor jewellery, gift and furnishings catalogue.

In the tradition of fine old-line trading companies, Willoughby & Taylor, Ltd. virtually travelled the globe in search of the unusual, the unique, the exquisitely beautiful and exotic merchandise seldom seen in the United States. Delicately wrought silver from England, shimmering crystal from Ireland, elegant pewter from a tiny village in Malaysia, jewellery from Spain, priceless pearls from Lake Biwa in Japan...

They have all been delivered to our American vaults and are waiting to be discovered by you.

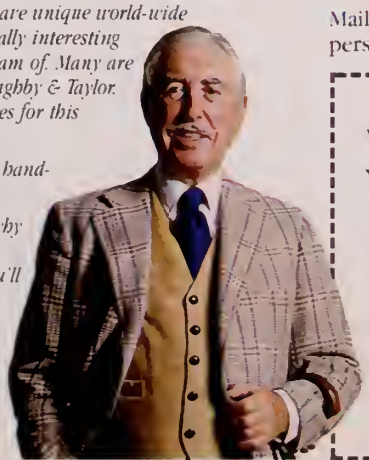
So send today for your own Willoughby & Taylor American Edition catalogue – and begin an adventure in discovery you won't soon forget.

Meissen of Germany. The oldest and most respected porcelain manufactory in Europe. Who else could have produced such an exquisite sample of porcelain artistry? Hand made and decorated by some of the world's finest living craftsmen, the charming Meissen duck is one of our most treasured discoveries.

The cool precision of the Masters of the Netherlands Renaissance finds expression today in this handcrafted mantelpiece clock from Holland. An ingenious blend of classical balance with rococo nuance of expression, its beauty is matched only by the precision of its timekeeping.

The serene beauty of the Orient is nowhere better demonstrated than in the centuries-old tradition of hand-lacquering. This beautifully made, hand-lacquered, hand-painted hardwood chest, decorated with the ancient symbol of the lotus, was found in a small trading village in Japan.

Since the time of the ancient Egyptians, lapis lazuli has been prized for its rich, azure-blue beauty and, some believed, its medicinal power. This distinctive gentleman's ring features a large, genuine lapis stone in a heavy ridged 14 karat gold mounting for a dramatically important look.



"I want to personally invite you to discover with me some of the rare treasures of the world.

"We at Willoughby & Taylor are privileged to have unique world-wide sources that allow us to locate the kind of really interesting and unusual items other merchants only dream of. Many are exclusive items available only through Willoughby & Taylor. Frankly, I rather think we're outdone ourselves for this American introduction.

"Everything in our catalogue was sought out, hand-picked and shipped over just for you.

"When you see it, I think you'll understand why we're especially proud of the job we're done. And should you decide to place an order, you'll learn why we are equally proud of the exceptional service we provide."

The Ecology Movement After Ten Years

The reports of its death are greatly exaggerated

by Betty Radcliffe and Luther P. Gerlach

Is the environmental movement dead or alive? According to the response to *Natural History*'s 1980 "You and the Ecology Movement" questionnaire, published in the July issue, ecological problems continue to be of vital interest to our readers. Comparisons with responses to a similar questionnaire published by *Natural History* in 1970 suggest that the movement is very much alive, although it has taken some new directions, influenced primarily by energy and inflation issues. Such comparisons must be made carefully, however, since only 7 percent of those who responded to the 1980 questionnaire remembered filling out the questionnaire in 1970.

Returns of the 1980 questionnaire came in from all fifty states, several U.S. territories, and several provinces of Canada, as well as from Brazil, Argentina, England, and a number of other countries. We received 3,941 questionnaires in time for coding and processing—three-fourths as many as we received in 1970. This is a remarkable response, considering that in 1970 concern with ecological problems seemed to be growing, while in 1980 many wondered if the environmental movement had been abandoned.

What sort of sample did we analyze and how far can our findings be generalized to the broader public? A profile of our admittedly self-selected sample appears in table 1. In considering the findings of our survey, it is necessary to keep in mind that those who filled in the questionnaire are highly educated and relatively affluent and that the largest percentage of them are in professional, educational, or social service occupations. The sample does not reflect *Natural History*'s entire readership but rather that portion interested enough or, in some cases, angry enough to participate in this survey.

The population sample is broken down into subgroups, according to age, sex, occupation, and levels of education and income. Differences between the various subgroups did appear in the responses to most of our questions, but these were usually differences only of degree, particularly on questions concerning attitudes toward movements in support of environmental protection, social justice, corporate responsibility, and sound energy development and toward more private activities focused on individual change and personal growth. Where significant differences between subgroups did show up, we found that greater percentages of younger people, no more than twenty-nine years old, and women of all ages working in professional, educational, and social service jobs and earning modest incomes tended to take positions that challenged the status quo, favoring both social and personal change. In contrast, men over sixty earning high incomes in engineering or technical occupations tended to have more conservative views. These findings were generally consistent with our 1970 results.

In both 1970 and 1980, many of the questions were designed to explore a broad range of cultural attitudes. The results of the two questionnaires,

Does anyone out there want to save money on history books?

(First price is publisher's list. **Boldface** shows member's price.)

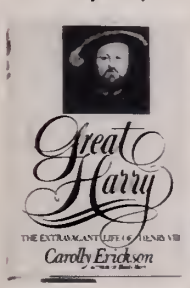
8656. **The Arthurian Legends: An Illustrated Anthology.** *Selected and introduced by Richard Barber.* Explores the influence of the Arthurian romance as interpreted through the ages. $19.50 / **$13.95**

2162. **Fire and Water: A Life of Peter the Great.** *By Alex de Jonge.* One of the world's most flamboyant rulers—one of history's most extraordinary stories. $12.95 / **$9.50**

8284 **The Devil's Horsemen: The Mongol Invasion of Europe.** *By James Chambers.* $11.95 / **$8.95**

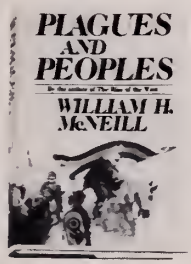
8870. **The Battle For Gaul.** *By Julius Caesar. Translated by Anne and Peter Wiseman.* $15.95 / **$11.50**

8953. **Crispin's Day: The Glory of Agincourt.** *By Rosemary Hawley Jarman.* The vivid medieval drama of Henry V's most famed campaign against the French. $15.00 / **$10.95**



2519 **John D.: The Founding Father of the Rockefellers.** *By David Freeman Hawke.* $12.95 / **$9.95**

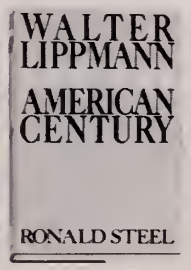
7518. **Antietam: The Photographic Legacy of America's Bloodiest Day.** *By William A. Frassanito.* $15.95 / **$10.25**



2956. **Germany: 1866-1945.** *By Gordon Craig.* $22.50 / **$14.50**

7765. **Richard the Lionheart.** *By John Gillingham.* Seen from a new perspective, this legendary king emerges as one of the ablest monarchs ever to sit on the British Throne $12.50 / **$8.50**

8250. **Babylon.** *By Joan Oates* $16.95 / **$10.95**



2279. $14.95 / **$10.50**

5207. $10.00 / **$7.75**

2428. $24.00 / **$14.00**

2667. $19.95 / **$13.95**

Consider how much you're spending to read the books you enjoy. Then, consider the alternative.

The History Book Club.

Last year, our members saved an average of 33% off publishers' prices on a variety of books, covering the entire history of man.

And to introduce you to the Club, we have an offer that can save you even more.

Shop this page. We'll send you any three of the books listed here (worth up to $74.00) for just 99¢. Plus a fourth at the low member's price. Just compare our member's prices to the publisher's prices listed below.

You need take only four more books in the next twelve months. After which you'll save even more on bonus books you may choose from our entire list. In your first year, your total savings, including this introductory offer, can be more than 50%.

You can count on getting the best new titles in the same kind of editions you'd find in bookstores. All at savings of $3, $4, $5 (and more), off bookstore prices.

Any three books for 99¢ with trial membership.

Membership Benefits. A membership account will be opened for you, to which your purchases will be charged at the low member's prices. You need pay only after you have received your books. A postage-and-packing fee is added to each shipment.

Every four weeks (13 times a year) you will receive our *Review* containing descriptions of new and recent selections. If you want the Editors' Choice, do nothing; it will be sent automatically. If you want another book, or no book at all, return the card by the date specified. If you should receive an unwanted book because you had less than ten days to decide, you may return it and pay nothing. We guarantee postage.

ND81A

The History Book Club
Stamford, Conn. 06904

Please enroll me as a trial member and send me the four books whose numbers I have entered below. Bill those on the left at 99¢ for all three and the fourth at the low member's price, plus postage-and-packing

I may return the books within three weeks at your expense and owe nothing. Or I will buy four more selections within a year (*not counting my choices above*). Membership is cancellable any time thereafter. All Club purchases are at low member's prices and a postage-and-packing fee is added to all shipments.

You can bring a beautiful animal into your life.

Today.

Lynn Chase, one of America's foremost animal painters, has recently produced two exceptional wild animal portraits in limited editions for discriminating collectors.

One to view.

The Pandas. This beautiful lithograph of three playful Pandas in their natural habitat has been produced in 12 colors on white Arches cover paper, 100% rag, imported from France. The image size is 18" x 35" on a 25½" x 38" sheet. Each print has been hand signed and numbered by Miss Chase in a limited editionof 400.
$150., sent first class mail in a tube.

One to wear.

The Jaguar. As sleek, smooth and beautiful in nature as on this limited edition Italian silk scarf, hand screened in 10 colors. Produced in Como, Italy on a generous 36" square of silk, each scarf has a hand rolled, contrasting hem and is hand signed and numbered by Miss Chase in an edition of 400. The scarf is suitable for framing.
$85., sent first class mail in a box.

Miss Chase's work has been exhibited in major American and European cities and is represented in as many collections here and abroad. Miss Chase has travelled extensively in Africa and is a member of the New York Safari Club, World Wildlife Fund, African Wildlife Leadership Foundation and the New York Zoological Society.

How to order.

To bring one (or both) of these beautiful animals into *your* life, send a check or money order for the edition selected, plus $1.50 for postage and handling, to Lairs Limited, PO Box 453 B Lenox Hill Station, New York 10021. Allow four weeks for delivery. New York State residents add applicable sales tax. You will receive a certificate of authenticity with each purchase.

LairsLimited

compared in table 2, reveal similarities and differences between the two samples, as well as between their respective subgroups. Population control, for example, was more of an issue in 1970 than in 1980. In 1970, the least controversial of all our statements about cultural attitudes was, "I think that all American families, regardless of social or economic position, must limit the number of children to two or, at most, three." There was an interesting pattern in the responses to this question in 1980: Those 60 and over agreed most strongly with the statement; those in the 30 to 59 group, somewhat less strongly; and those 29 and younger, least of all. We also found that the less income people had, the more strongly they agreed with the statement.

On other questions the 1980 sample showed slightly more faith in technology as a way to solve environmental problems and in the adequacy of present laws and conventions governing the use of natural resources on private lands. Those responding to the 1980 questionnaire were also more apt to believe that economic growth is good for any community and less apt to feel that the profit motive is outdated. In general, the 1980 sample believed that environmental problems are connected to economic, technological, and political problems.

Some attitudes have apparently not changed in the last decade. Two statements drew almost exactly the same response on the two questionnaires. Both samples strongly disagreed with the idea that plants and animals exist primarily for human use and enjoyment, and both were fairly evenly divided on whether our ecological problems can be solved by existing American political and economic systems.

The two questionnaires themselves were not exactly the same. In 1980, we included several new questions reflecting the tremendous role energy issues have come to play in the last decade. We knew that many people, including both those whose professions involve them in energy issues and those whose concern is more general, believe that the Western industrial nations' present dependence on imported petroleum is a significant threat to those nations' economic stability. Many who hold this view believe that, at least for the short term, the best solution to this problem is to derive more electricity from nuclear and coal-fired plants and, increasingly, from large, centralized solar energy

Table 2

Cultural Attitudes

		% Agree	% Disagree
Plants and animals exist for our benefit	1970	*	81.0
	1980	15.3	80.5
Technology can solve environmental problems	1970	18.0	*
	1980	25.0	61.3
Private-property owners should be able to use their property according to current laws	1970	*	75.0
	1980	32.9	48.3
The profit motive is outdated and must change	1970	55.0	33.0
	1980	41.7	45.9
Our current political and economic system can solve environmental problems	1970	37.0	45.0
	1980	38.7	46.2
Population growth must be controlled	1970	79.0	*
	1980	63.7	27.4
Economic growth is good for any community	1970	20.0	63.0
	1980	29.6	52.8
Individuals have personal responsibility for pollution	1970	62.0	*
	1980	96.5	2.2

*Data not available

facilities. A massive shift to fossil-based synthetic fuels is often envisioned as part of this scheme. But other people fear that plans such as these and, more generally, the pressure to become energy independent may jeopardize the environmental victories won thus far. It was to investigate these varied views and to gain insight into how people feel energy issues relate to environmental issues that we revised the 1980 questionnaire.

The analysis of the responses to these questions told us, first of all, that the people in our sample think in terms of systems. The many comments we received chiding us for offering simplistic choices or for demanding single solutions to complex problems certainly suggest this interpretation. Asked at what level major problems related to the pollution and degradation of our air, water, and land can best be solved, the majority felt that we should "increasingly manage these problems as parts of complex systems on state, federal, and international levels." Half chose "lack of [a] coherent, effective national energy policy" as our main energy problem.

We also saw in the 1980 sample that there was a strong sentiment for turning to renewable energy resources. Nearly 90 percent of those who responded to the questionnaire were in favor of movements promoting the development of solar technology, if not actually active in such movements (see table 3). In fact, even those who disapproved of most other activist organizations tended to support the solar energy movement. Furthermore, a full three-fourths of the sample agreed with the statement, "I think we are indeed running out of fossil-based fuels."

In general, however, this sentiment did not seem to be linked to a desire to see alternative energy systems supplant more conventional ones. More than half the responses indicated that "integrating conventional fossil-fuel technologies and renewable-energy alternatives in both centralized and decentralized, [and] large and small systems" was the most desirable way to achieve a better, more adaptive energy future. The majority of the people who responded also felt that "improving communication to the public of scientific concepts and technological facts about nuclear and fossil-based fuels" would most effectively resolve current conflicts over energy development.

Table 3

Movements in 1980 and Attitudes Toward Them

	For environmental protection	For social justice	Against large-scale, centralized energy development	For solar energy	For corporate responsibility	For individual change
Active in	26.9%	13.6%	9.5%	11.1%	8.2%	12.3%
Favor/not active	43.7	48.1	38.6	76.5	68.8	18.2
Agree with goals, but not all methods	20.2	25.4	16.7	3.8	10.9	18.0
Uncertain	2.2	3.5	7.5	5.6	5.3	27.4
Disapprove of	4.9	7.3	20.4	2.4	4.9	21.0
Disapprove and want suppressed	1.9	2.0	7.3	0.4	1.7	3.0

The responses to the 1980 questionnaire did not tell us how the role of nuclear energy in the future is viewed. More than half of those who responded were "concerned that using nuclear sources for energy may seriously endanger human life on this planet," and one-third selected "nuclear and other hazardous-waste buildup and storage" as "our most critical environmental problem." On the other hand, close to a third disapproved of the category of activist movements that included antinuclear protests. According to many who wrote to us, our coupling of protests against nuclear power with protests against other large-scale, centralized energy-development projects was inappropriate. Some who wrote in told us that they felt greater concern about the more immediate effects of acid rain and the greenhouse effect of burning increased amounts of fossil fuels than they did about the risks of nuclear power.

The various movements to change individuals, either through personal experience, such as meditation, or through interpersonal experiences, such as self-help or sensitivity groups, also drew considerable disapproval. Judging from the comments on returned questionnaires and the letters we received, people generally associated this category with the Eastern religions and such activities as biofeedback groups and transcendental meditation. We had intended the category to include the Christian evangelical "born again" and charismatic movements, but perhaps it is just as well that the people who responded to the questionnaire did not seem to share this interpretation. The explicit coupling of these diverse movements in the same category would have probably elicited the same kind of negative response that our linking of antinuclear protests to protests against other energy projects did.

In general, however (as shown in table 3), the people who responded to the 1980 questionnaire approved of movements and activities undertaken in support of them. We have already indicated the high approval of solar energy movements. The next most favored forms of activism were movements "to make corporations more accountable for actions believed to place at risk the health and welfare of workers and consumers here and in other countries." Interestingly, there was also much support—more than 80 percent—for "boycotting companies that don't seem environmentally or socially responsible." As table 4 shows, next to writing letters, boycotting was the form of activity most frequently engaged in to influence decision makers. Campaigns to hold corporations accountable for their actions have often been associated with church-related organizations, but a majority of those who did not believe that "churches should be actively involved in the critical social and environmental issues of the day" still favored such actions.

According to many who responded to the 1980 questionnaire, the various movements against large-scale energy development and in favor of environmental protection, social justice, corporate responsibility, and personal change are all interrelated. Nearly half saw "some connection between some of them," and almost a fifth

Table 4

Methods of Influencing Decision Makers in 1980

	Action approved	Action taken
Letter writing	94.1%	56.9%
Speaking at public hearings	85.5	24.3
Environmental lawsuits	77.4	7.9
Boycotts	83.1	43.1
Rallies, marches, demonstrations	58.7	20.2
Nonviolent direct action	43.2	4.1
Office sit-ins	15.7	1.0
Destructive or violent action	7.8	.8

ANIMALS SHOWN APPROXIMATELY ACTUAL SIZE

The Woodland Animals

MINIATURE PEWTER SCULPTURES

Twelve beautifully detailed sculptures by the gifted artist Jane Lunger, meticulously crafted in fine pewter, and affordably priced at just $12.50 each.

Available by subscription only, exclusively from The Franklin Mint. Please order by February 10, 1981.

Imagine—for just a moment—that you're standing in a quiet forest glade. It's early morning, and sunlight filters softly through the trees. You brush aside a screen of leaves . . . and there, nestled in the undergrowth, is a baby fawn.

This is part of the magic that inspired Jane Lunger to create a wonderful new collection. *The Woodland Animals Miniature Pewter Sculptures.* Twelve endearing pewter figures—each no more than two inches high—yet each engagingly true to life.

Each miniature a small masterpiece of design and detail

Sculptor Jane Lunger has been acclaimed for her remarkable ability to capture all the spirit and grace of wild animals. For this collection, she has portrayed twelve forest creatures with amazing warmth and realism . . . so that every one of the animals is brought to life in a charmingly original work of art.

Here is the fox, curled up amid clusters of wild violets. He's at rest, but his ears are perked to catch the faintest sound. The beaver munches contentedly on a finely-veined aspen leaf. The fluffy-tailed squirrel seems to be chattering impudently at you from his perch in a tree.

And each original pewter sculpture is richly detailed—so that you can see the most subtle nuances of form and expression . . . and practically *feel* the texture of each animal's fur.

Jane Lunger selected the medium of fine pewter because this metal is unsurpassed in its ability to capture such fine detail. Master pewterers of The Franklin Mint—renowned the world over for their skill—will devote their attention to each work. Every sculpture will be *individually finished* to highlight the lustrous beauty of the pewter itself.

Exceptional quality . . . at a very affordable price

Despite the care and time that must be taken with every sculpture, these original works will be available at the extremely reasonable price of $12.50 each. This price is guaranteed for all subscription applications received by February 10, 1981. *The Woodland Animals* are available exclusively from The Franklin Mint, and only as a complete collection.

Because they so perfectly combine art and nature, these beautifully crafted miniatures will be endlessly fascinating for you, your family, and friends. As a collection, they will be a delight to display in your home.

There is no need to send any money at this time. Please keep in mind, however, that the subscription application should be signed and mailed to The Franklin Mint, Franklin Center, Pennsylvania 19091 by February 10th.

© 1980 FM

At The Franklin Mint, we take pride in our standards of design and craftsmanship. But we believe our efforts should be judged by the people we serve. Any figure may be returned for any reason within thirty days for replacement or refund.

Better Than Jogging

NordicTrack

Jarless Total Body Cardiovascular Exerciser Duplicates X-C Skiing for the Best Motion in Fitness

This revolutionary new exerciser duplicates the smooth, rhythmic, total body motion of X-C skiing for the most effective cardiovascular exercise obtainable. Uniformly exercises more muscles than any other exercise device. Makes high heart rates easy to obtain and keeps more muscles in tone. Also highly effective for weight reduction.

Completely jarless natural motion does not cause joint and back problems as in jogging or running. Arm and leg resistances are separately adjustable for maximum effectiveness. The NordicTrack uses no motors and folds compactly for convenience. Used in homes, businesses, and institutions. Our customers include Xerox Corporation, US Army, Penn State U and the YMCA.

For more info write or call: 612-448-6987
PSI 124 L Columbia ct. Chaska, MN 55318

agreed that the movements were "all aspects of one single wave of revolutionary change." More than half thought "environmental degradation, social injustice, and economic inequality are part of the same basic problem in our society."

The returns of both the 1970 and the 1980 questionnaires indicate that people who believe issues and movements are connected reflect this belief in their actions. Of all the activist movements described in the 1980 forms, the environmental movement claimed the most followers. Of these environmental activists, about one-fourth have overlapping memberships in movements promoting social justice or solar energy, more than a fourth in movements against large-scale energy development plans, and almost a fifth in movements for corporate responsibility.

In both 1970 and 1980 we asked what actions people were taking to express their beliefs about the environment, and the answers to this question revealed a significant difference between the two samples. For example, in 1970, more than 25 percent of those responding to the questionnaire made contact with people involved in environmental organizations three or more times a week. In 1980, only 5 percent had this much contact, and most had no more than a few such encounters each year. In general, activists in the 1970 sample seemed to be part of a young, grass-roots movement, whereas today's activists work within a much more formal, bureaucratic framework and interact with government and industry according to established routine.

Table 5

Life-Style Changes in 1980

Used fewer disposables	67.0%
Recycled garbage	47.5
Modified home to save fossil-based energy	53.8
Changed residence to save energy	20.1
Did not use air-conditioner or recreational vehicle	40.4
Car-pooled or used public transit	43.7
Used smaller car	59.0
Reduced use of motors for recreation	54.9
Visited wilderness areas	36.7
Sought self-sufficient country living	17.6
Changed food habits	2.6
Other conservation of energy activities	8.9
Other preservation of environment activities	2.3
Other	12.1

The 1970 and 1980 questionnaires emphasized not only movements but also change—personal as well as social. And although the 1980 responses revealed less participation in organized environmental activities than the 1970 responses, more than half the people who responded in 1980 indicated that their "involvement with environmental organizations had changed [their] ideas about [themselves] and led [them] to act differently." People active in any one environmental organization tended to be active in several: three-fourths of those who reported membership in groups concerned with environmental problems belonged to two or more, and a third of these belonged to four or more.

Finally, the 1980 sample is characterized by a sense of individual responsibility for environmental problems. More than 95 percent agreed with what was apparently our least controversial question: "I believe I have personal responsibility in the fight against pollution." To get another measure of this level of involvement, we gave examples of personal actions that are commonly believed to contribute to a higher-quality environment and asked our respondents to tell us which of these actions they had taken (see table 5). Not everyone would agree that all these actions are directly related to improving the environment, but because most are either costly or time consuming, we feel they indicate commitment to ecological principles. Close to 60 percent of our sample listed from four to seven of these activities.

In summary, environmental matters are still very important to *Natural History* readers. If our sample is any guide, a decade after Earth Day the environmental movement is most alive on an individual level, with many people choosing to express their ecological concern in their everyday lives. □

Fill out this coupon and save the children

Complete this simple questionnaire, and befriend a needy child through Save the Children. For only fifty-two cents a day, your money, combined with that of other sponsors, can breathe new life into an impoverished village...help hardworking people in their fight for dignity...turn despair into hope for a child who has known only disaster. Fifty-two cents may not buy much where you live. But for the poorest of the poor where the need is so desperate, it can work miracles. NH 1/1

My Name Is _____
(please print)

Address _____

City _____ State _____ Zip _____

Tell us how you want to help, by answering these questions:

1. What kind of child would you like to help?

☐ Boy ☐ Girl ☐ No preference

2. What geographical area are you interested in?

Urgent need exists in all the areas listed below, especially overseas. If you have a strong preference for a particular location, check the area of your choice. If not, won't you please let us assign a child where the need is greatest?

☐ **Certainly. Choose a child for me in an area of greatest need.**

I strongly prefer:

☐ Africa
☐ Bangladesh
☐ Chicano (U.S.)
☐ Colombia
☐ Dominican Republic
☐ Honduras
☐ Indian (U.S.)
☐ Indonesia
☐ Inner Cities (U.S.)
☐ Israel
☐ Korea
☐ Lebanon
☐ Mediterranean
☐ Mexico
☐ Southern States (U.S.)
☐ Sri Lanka (Ceylon)

3. Would you like a picture of your sponsored child?

Shortly after we select a child for you, we can send you a photograph and brief personal history, if you desire.

☐ Yes ☐ No

4. Would you like to exchange correspondence?

If desired, correspondence can build a meaningful one-to-one relationship and provide a unique educational experience for the sponsored child. In areas where illiteracy is high, a village representative will keep you informed of the progress your child is making. Translations, where necessary, are supplied by Save the Children.

☐ Yes ☐ No

5. Would you like information about the child's community?

Several times a year you can receive detailed reports on the activities and projects being undertaken in the community to benefit your sponsored child. These community reports show how your money is being used most effectively for permanent improvements to the child's environment—for health care, education, food production, nutrition, and community training. Would you like to receive such information?

☐ Yes ☐ No

6. How do you wish to send your sponsorship contribution?

Enclosed is my check for $

☐ Monthly, $16 ☐ Semi-annually, $96
☐ Quarterly, $48 ☐ Annually, $192

7. Do you wish verification of Save the Children credentials?

Save the Children is indeed proud of the handling of its funds. Based on last year's audit, an exceptionally large percentage (80.3%) of each dollar spent was used for program services and direct aid to children and their communities. Due to volunteered labor and materials, your donation provides your sponsored child with benefits worth many times your total gift. Would you like to receive an informative Annual Report (including a summary financial statement)?

☐ Yes ☐ No

(A complete audit statement is available upon request.)

8. Would you rather make a contribution than become a sponsor of an individual child at this time?

☐ Yes, enclosed is my contribution of $_____.

☐ Check here for general information about our unique programs for aiding impoverished children.

The Politics of Census

Although the latest United States census contains systematic but honest errors, some nineteenth-century counts may have been fraudulent

by Stephen Jay Gould

In the Constitution of the United States, the same passage that prescribes a census every ten years also includes the infamous statement that slaves shall be counted as three-fifths of a person. Ironically, and however different the setting and motives, black people are still being undercounted in the American census. In Detroit, on September 25, 1980, federal judge Horace W. Gilmore invalidated the 1980 census because poor people in inner cities—primarily blacks and Hispanics—had been systematically missed.

The census has always been controversial because it was established as a political device, not as an expensive frill to satisfy curiosity and feed academic mills. The constitutional passage that ordained the census begins: "Representatives and direct taxes shall be apportioned among the several states which may be included within this union, according to their respective numbers."

Political use of the census has often extended beyond the allocation of taxation and representation. The sixth census of 1840 engendered a heated controversy based upon the correct contention that certain black people had, for once, been falsely *over*-counted. This curious tale illustrates the principle that copious numbers do not guarantee objectivity and that even the most careful and rigorous of surveys are only as good as their methods and assumptions. It should also help us to understand why, contrary to common sense, even an honest attempt to count everyone may be one of the worst ways to determine our population. (William Stanton tells this story in *The Leopard's Spots,* his excellent book on the history of scientific attitudes toward race in America during the first half of the nineteenth century. I have also read the original papers of the major protagonist, Edward Jarvis.)

The 1840 census was the first to include counts of the mentally ill and deficient, enumerated by race and by state. Dr. Edward Jarvis, then a young physician but later to become a national authority on medical statistics, rejoiced that the frustrations of inadequate data would soon be overcome. He wrote in 1844:

> The statistics of insanity are becoming more and more an object of interest to philanthropists, to political economists, and to men of science. But all investigations, conducted by individuals or by associations, have been partial, incomplete, and far from satisfactory. . . . They could not tell the numbers of any class or people, among whom they found a definite number of the insane. And therefore, as a ground of comparison of the prevalence of insanity in one country with that of another, or in one class or race of people with that in another, their reports did not answer their intended purpose.

Jarvis then praised the marshals of the 1840 census as apostles of the new, quantitative order:

> As these functionaries were ordered to inquire from house to house, and leave no dwelling—neither mansion nor cabin—neither tent nor ship unvisited and unexamined, it was reasonably supposed that there would be a complete and accurate account of the prevalence of insanity among 17 millions of people. A wider field than this had never been surveyed for this purpose in any part of the earth, since the world began. . . . Never had the philanthropist a better promise of truth hitherto undiscovered. . . . Many proceeded at once to analyze the tables, in order to show the proportion of lunacy in the various states, and among the two races, which constitute our population.

As scholars and ideologues of varying stripes scrutinized the tables, one apparent fact rose to obvious prominence in those troubled times. Among blacks, insanity struck free people in northern states at a vastly greater frequency than it afflicted slaves in the South. In fact, one in 162 blacks was insane in free states, but only one in 1,558 in slave states. But freedom and the North posed no mental terror for whites, since their relative sanity did not differ in the North and South.

Moreover, insanity among blacks seemed to decrease in even gradation from the harsh North to the congenial South. One in 14 of Maine's black population was either insane or idiotic; in New Hampshire, one in 28; in Massachusetts, one in 43; in New Jersey, one in 279. Reaching Delaware, however, the frequency of insanity among blacks suddenly nose-dived. As Stanton writes: "It appeared that Mason and Dixon had suveyed a line not only between Maryland and Pennsylvania but also—surely all unwitting—between Sanity and Bedlam."

In his first publication on the 1840 census, Jarvis drew the same conclusion that so many other whites would advance: slavery, if not the natural state of black people, must have a remarkably beneficent effect upon them. It must exert "a wonderful influence upon the development of moral faculties and the intellectual powers." A slave gains equanimity by "refusing many of the hopes and responsibilities which the free, self-thinking and self-acting enjoy and sustain," for bondage "saves him from some of the liabilities and dangers of active self-direction."

The basic "fact" of ten times more insanity in freedom than in slavery was widely bruited about in the contemporary press, often in lurid fashion. Stanton quotes a contributor to the *Southern Literary Messenger* (1843) who, concluding that blacks grow

Managing Chemical Wastes

What the chemical industry is doing to improve waste-disposal methods

America's chemical companies have already invested hundreds of millions of dollars in safer, better waste-disposal methods. We'll spend over $2 *billion* more on waste-disposal facilities in the next two years. Here's how we're advancing the "state of the art":

1. Eliminating wasteful processes

We're redesigning manufacturing processes and improving efficiency. We're adding on-line treatment systems to neutralize, reduce in volume or change the nature of waste by-products. We're also using recovery techniques that let us recycle wastes back into the production process. One company, for example, is salvaging phenol, used to manufacture plastics, pharmaceuticals and other useful products.

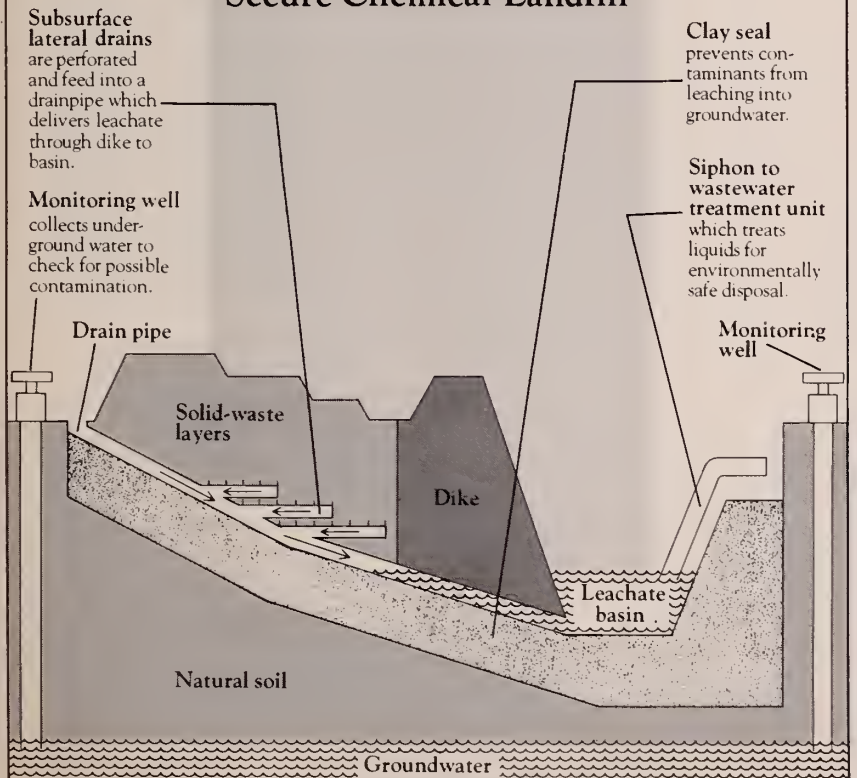
2. Building secure landfills

Secure landfills have a barrier that keeps wastes from seeping out into groundwater and keeps groundwater from migrating through the landfill. Other features may include facilities for recycling liquids or a wastewater treatment unit to clean up liquids for safe disposal. Landfills—if *properly* designed, operated and monitored—are one of the best ways to dispose of many kinds of solid wastes.

3. Continuing industry commitment

We were finding ways to manage solid wastes long before the nation recognized the need for better waste-disposal methods. In fact, we already had much of the required waste-disposal technology and remedial strategies in place—or being developed—when Congress passed the Resource Conservation and Recovery Act of 1976, which sets forth strict waste-disposal guidelines.

4. Sharing knowledge and new technology



As we develop new waste-disposal techniques, we share our knowledge with industry, government and the public. In 1979, we began conducting a series of regional seminars that presented current techniques for solid-waste disposal. Individual companies may use videotapes, visual aids or other techniques to train personnel in waste-disposal methods.

5. Encouraging solid-waste exchanges

Sometimes one chemical company's wastes can become another company's raw material. Fluoride wastes from a phosphoric acid plant, for example, can be used by a company producing aluminum. So the chemical industry has encouraged the development of waste-exchange organizations, which develop and distribute lists of available wastes.

For a booklet that tells more about what we're doing to protect the environment, write to: Chemical Manufacturers Association, Dept. HL-101, Box 363, Beltsville, MD 20705.

Secure Chemical Landfill

Depending on the solid waste, the chemical industry selects disposal techniques such as incineration, by-product recovery, stabilization or secure landfill design to protect the environment.

"more vicious in a state of freedom," painted a frightful picture of Virginia should it ever become a free state, with "all sympathy on the part of the master to the slave ended." He inquired:

> Where should we find penitentiaries for the thousands of felons? Where, lunatic asylums for the tens of thousands of maniacs? Would it be possible to live in a country where maniacs and felons meet the traveler at every crossroad.

But Jarvis was troubled. The disparity between North and South made sense to him, but its extent was puzzling. Could slavery possibly make such an enormous difference? If the information had not been stamped with a governmental imprimatur, who could have believed it? Jarvis wrote:

> This was so improbable, so contrary to common experience, there was in it such a strong prima facie evidence of error, that nothing but a document, coming forth with all the authority of the national government, and "corrected in the department of state," could have gained for it the least credence among the inhabitants of the free states, where insanity was stated to abound so plentifully.

Jarvis therefore began to examine the tables and was shocked by what he discovered. Somehow, and in a fashion that could scarcely represent a set of random accidents, the number of insane blacks had been absurdly inflated in reported figures for northern states. Jarvis discovered that 25 towns in the 12 free states contained not a single black person of sound mind. The figure for "all blacks" had obviously been recopied or misplaced in the column for "insane blacks." But data for 135 additional towns (including 39 in Ohio and 20 in New York) could not be explained so easily, for these towns actually reported that their population of insane blacks exceeded their total number of blacks, both sane and unhinged!

In a few cases, Jarvis was able to track down the source of error. Worcester, Massachusetts, for example, reported 133 insane in a total black population of 151. Jarvis inquired and discovered that these 133 people were white patients living in the state mental hospital located there. With this single correction, the first among many, black insanity in Massachusetts dropped from one in 43 to one in 129. Jarvis, demoralized and angry, began a decade of unsuccessful campaigning to win an official retraction or correction of the 1840 census. He began:

> Such a document as we have described, heavy with its errors and its misstatements, instead of being a messenger of truth to the world to enlighten its knowledge and guide its opinions, it is, in respect to human ailment, a bearer of falsehood to confuse and mislead.

This debate was destined for a more significant fate than persistent bickering in literary and scholarly journals. For Jarvis's disclosures caught the ear of a formidable man: John Quincy Adams, then near eighty, and capping a distinguished career as leader of antislavery forces in the House of Representatives. But Adams's opponent was equally formidable. At that time, the census fell under the jurisdiction of the Department of State, and its newly appointed secretary was none other than John C. Calhoun, the cleverest and most vigorous defender of slavery in America.

Calhoun, in one of his first acts in office, used the incorrect but official census figures in responding to the expressed hope of the British foreign secretary, Lord Aberdeen, that slavery would not be permitted in the new republic (soon to be state) of Texas. The census proved, Calhoun wrote to Aberdeen, that northern blacks had "invariably sunk into vice and pauperism, accompanied by the bodily and mental afflictions incident thereto," while states that had retained what Calhoun called, in genteel euphemism, "the ancient relation" between races, contained a black population that had "improved greatly in every respect—in number, comfort, intelligence, and morals."

Calhoun then proceeded to evade the official request from the House, passed on Adams's motion, that the secretary of state report on errors in the census and steps that would be taken to correct them. Adams then accosted Calhoun in his office and recorded the secretary's response in his diary:

> He writhed like a trodden rattlesnake on the exposure of his false report to the House that no material errors had been discovered in the printed Census of 1840, and finally said that there were so many errors they balanced one another, and led to the same conclusion as if they were all correct.

Jarvis, meanwhile, had enlisted the support of the Massachusetts Medical Society and the American Statistical Association. Armed with new data and

A POTPOURRI FROM QPB

QPB brings you a great selection of titles from a wide range of fiction and nonfiction. Humor. History. Poetry. Classic and current and of lasting interest.

All are printed on fine paper in readable type. And all are full-size, softcover editions just as durably bound as their hardcover counterparts. Yet they cost up to 65% less. Why pay for the hardcover? Join QPB and pay for the part you read. The inside.

support, Adams again persuaded the House to ask Calhoun for an official explanation. And again Calhoun wriggled out, finally delivering a report full of obfuscation and rhetoric, and still citing the 1840 figures on insanity as proof that freedom would be "a curse instead of a blessing" for black slaves. Jarvis lived until 1884 and assisted in the censuses of 1850, 1860, and 1870. But he never won official acknowledgment of the errors he had uncovered in the 1840 census; the finagled, if not outrightly fraudulent, data on insanity among blacks continued to be cited as an argument for slavery as the Civil War approached.

There is a world of difference between the overcount of insane blacks in 1840 and the undercount of poor blacks (and other groups) in central cities in 1980. First, although the source of error in the 1840 census has never been determined, we may strongly suspect some systematic, perhaps conscious manipulation by those charged with putting the raw data in tabular form. I think we can be reasonably confident that, with automated procedures and more deliberate care, the systematic errors of the 1980 census are at least honest ones. Second, the politics of 1840 left few channels open to critics, and Calhoun's evasive stubbornness finally prevailed. Today, nearly every census is subjected to legal scrutiny and challenge. Indeed, a few days after Judge Gilmore ruled the 1980 census invalid until its errors can be corrected, Judge Henry F. Werker of Manhattan held that the Census Bureau may use statistical adjustments (rather than actual recounts) to rectify its figures.

But a strong similarity also connects 140 years. The prestige of the census, invoked with such skill by Calhoun to divert his critics, still prevents the reform that might curtail its persistent and systematic errors. This prestige arises from the mystique of quantification, the idea that numerical form renders information more rigorous, if not unassailable. But numbers are only as good as the procedures used to gather them; if methods are flawed, sheer accumulation advances us not one whit further toward accuracy. Second, the peculiar form of quantification used by the census gives it an air of invincibility. For the American census is not a statistical operation at all. It does not attempt to infer properties of the whole from samples. It actually tries to count the whole by direct, exhaustive enumeration. At first glance, what could be fairer and less subject to systematic error? Surely, a procedure of inference from samples offers more opportunity for bias.

If it were possible (however expensive) to count the whole with confidence, then no valid complaint could be raised. But it is not, and the very attempt to do so engenders a systematic error that guarantees failure. For some people are much harder to find than others, either by their direct resistance to being counted (illegal aliens, for example) or by the complex of unfortunate circumstances that renders the poor more anonymous than other Americans.

Regions with a concentration of poor people will be systematically undercounted, and such regions are not spread across America at random. They are located in the heart of our major cities. A census that assesses population by direct counting will be a source of endless contention so long as federal money and representation in Congress reach cities as rewards for greater numbers.

Ironically, the common-sense idea of simply counting everybody is probably the worst, and certainly the most expensive, way to conduct a census. Schemes of careful sampling and inference—a perfected version of the methods used to compile television-rating statistics, for example—would do a better job. At least they would attempt to deal explicitly with recognized biases and might reduce or eliminate systematic errors that arise from the flawed design of trying to count everyone when it cannot be done.

Censusing has always been contentious, especially since its historical purpose has usually involved taxation or conscription. When David, inveigled by Satan himself, had the chutzpah to "number" Israel (I Chronicles, chapter 21), the Lord punished him by offering some unpleasant alternatives: three years of famine, three months of devastation by enemy armies, or three days of pestilence (all reducing the population, perhaps to countable levels). The legacy of each American census will be ten years of contention, at least until we realize that counting noses is not the best way to enumerate vast numbers of varied people.

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

Get the Lion's share!

High Yields. Plus

Daily dividends!
Daily compounding!
Daily liquidity!

You get all this when you invest in Dreyfus Liquid Assets, the high yielding money market fund:

Dividends are declared and compounded daily. You get free checks for cash as you need it, or to pay larger bills. And you keep on earning today's high money market yields until your redemption check clears.

There is no sales charge, there's no penalty for early withdrawals--you can even redeem your investment by phone. Start with just $2,500. Additions can be as low as $100.

Neanderthal the Hunter

He was a superpredator. He was stunningly strong. He killed mammoths and woolly rhinos at close quarters. But he was finished when the climate turned warm

by Valerius Geist

When examining the fossils of some long-extinct creature, paleontologists accept the proposition that its manner of living and the food it ate are expressed in the shapes and dimensions of its bones. If the fossilized cheek teeth of an herbivorous mammal, for example, are long, open rooted, and wide, the animal lived on abrasive forage. If the body size of the animal is small, we can safely assume that the forage consumed was highly digestible. Therefore, the abrasiveness of the forage could not be due to a high fiber content, but must result from sand and dust particles adhering to the exterior of the plant material. Also, most modern small-bodied ungulates occur in warm regions. It follows then that the extinct ungulate in question occupied a habitat that was most likely a warm, dusty, windswept, sparsely vegetated steppe.

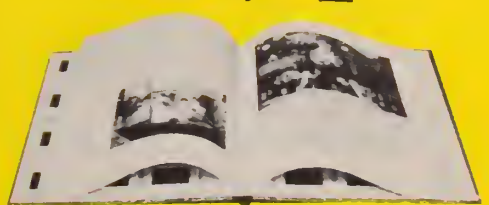
To test this proposition, the skull and postcranial skeleton should be examined. Are the eye orbits large? Is the skeleton that of a cursorial form? Are the tarsals and carpals fused into long, slender bones and the lateral digits greatly reduced to facilitate fast running over hard ground? The weapon system and the relative size of the sexes are other anatomical clues useful in determining the type of animal involved. If the hornlike organs are as complex as those used in wrestling and pushing matches by most contemporary deer and antelopes, we are likely dealing with a highly gregarious animal. The same conclusion can be reached if the weapons are greatly reduced or absent. Weapons that are used only to damage body surfaces, and thereby maximize pain, are incompatible with gregariousness. If the differences in body size between sexes are also negligible, we can be quite certain that the sexes lived together year-round in large herds.

Each conclusion is based on parallels with living forms, while the validity of the reconstruction is derived in good measure from the fact that each adaptation fits logically into a pattern. Such a pattern is called a strategy, or more precisely, an adaptive strategy. A strategy is composed of tactical components that must fit flawlessly with one another. The more components and the more complex their mutually supporting web, the more likely is the envisioned adaptive strategy. Microfossils and pollen found in association with the bones can further test the reconstruction.

I would like to use the same procedure to reconstruct the basic adaptive strategy of one of the most enigmatic humans from the past—Neanderthal. To do this, I shall attempt to link into one logical pattern the anatomical peculiarities of Neanderthal people, the characteristics of their tools, their large hearths filled with bone ash, their kill patterns of large mammals, and their precipitous disappearance. The information painstakingly assembled by archeologists will be useful, but an understanding of the peculiar periglacial landscapes Neanderthals inhabited and of the biology of large, dangerous mammals—their chief food—is crucial.

Periglacial landscapes, land greatly affected by the edges of continental and cordilleran glaciers, were often characterized by a mosaic of productive habitats with cold climate floras. The major habitats were fertile, dusty, loess steppes and rich grasslands on moist sites. These owed their existence to huge amounts of rock flour ground by the ice masses and spewed out with meltwater. This highly fertile ground-up rock was deposited as silt by meltwaters from the glaciers, and wherever it was desiccated by exposure to sun and air, it was carried away as loess by the strong winds coming from the ice masses. The annual pulses of ground rock and water created what is technically called a pulse-stabilized, immature ecosystem. This ecosystem, with its different habitats, was host to a highly diverse, dense megafauna of large grazers and large carnivores. It is no accident that in colonizing cold landscapes, humans inhabited the rich periglacial landscapes first and the unproductive tundra (a major interglacial habitat) tens of thousands of years later, in fact only within historic times. Nor is it an accident that the major breadbaskets of today are

24 Impressionist Masterpieces



ON 35mm. COLOR SLIDES for only $1

Please enter my trial subscription and send me the complete *Color Slide Album of Impressionist Painting*, including 24 color slides and 48-page illustrated art book. Bill me only $1, plus a few cents for tax and shipping. If I am not delighted with this introductory package, I may return everything within 15 days, cancel my subscription, and owe nothing.

If I do continue, you will send me a new Color Slide Album approximately every six weeks (for 15 days trial examination) and bill me at the subscribers' low price of $12.95, plus tax and shipping. I may take as few or as many Albums as I like, and may stop whenever I wish. After my fourth shipment I will be given a choice of receiving all remaining Albums at once, or continuing with single-album shipments.

☐ Check here if you wish the Kodak Carousel BC 604 Projector, and remit low subscribers price of only $99.50 plus tax with this card in envelope addressed to McGraw-Hill Color Slide Program of Art Enjoyment. If not delighted, return projector within 15 days for full refund

This offer applies to U.S. only

24 COLOR SLIDES of the Great Impressionist Masterpieces for only $1

(comparable value $18 to $24)

Includes this Deluxe Album and 48-page Gallery Lecture Guide—at no extra cost

Here's what you get for only $1

Luncheon on the Grass—Edouard Manet
Women in the Garden—Claude Monet
The Green Parasol—Berthe Morisot
Nude in the Sun—Auguste Renoir
The Seated Bather—Auguste Renoir
The Pedicure—Edgar Degas
The Saint-Lazare Railroad Station—Claude Monet
The House of Pere Lacroix—Paul Cezanne
The Saint-Martin Canal—Alfred Sisley
At the Races—Edgar Degas
The Red Roofs—Camille Pissarro
The Loge—Mary Cassatt
. . . plus 12 other Impressionist classics!

The Color Slide Program of Art Enjoyment

GAZE in astonishment as Renoir's lovely "Seated Bather" (shown above) appears on your wall aglow with all the vibrant reds, blues and greens of the Impressionist palette. Or, thrill to Rembrandt's famed "Aristotle Contemplating the Bust of Homer"—one of the world's costliest works of art. Or, marvel as you view Titian's allegorical masterpiece "Sacred and Profane Love" just as it appears in Rome's Borghese Gallery.

Until today, unless you had the means to travel among the world's great museums and private collections, you simply could not know these paintings so *intimately*. Now, as a member of the *McGraw-Hill Color Slide Program of Art Enjoyment*, they are but a few of the magnificent art works you will enjoy and more richly understand as you view them in dramatic *full-size* and glowing *original colors!*

Accept this $1 demonstration offer

If you mail the attached card, you will receive a unique Album containing 24 color slides of priceless works by Renoir, Monet, Degas and other important Impressionist painters. These exquisite slides are produced to exacting specifications in Florence on 35mm. Kodak film. They come in individual 2" x 2" mounts and can be used in any home slide projector. (If you do not own a projector, see special offer below.)

The color slides, however, are only one part of this elaborate Album. Bound into the center is an illustrated 48-page book by Albert Chatelet, Director of France's renowned Lille Museum—with a guide to each of the slide pictures and the complete story of the Impressionist era.

If this demonstration pleases you, you will be offered a new slide-and-commentary Album approximately every six weeks. Among the Albums in this series are *Italian Renaissance Painting*, the *Origins of Modern Art—Romanticism* and *Realism*—and other Albums covering every major art period.

The cost is surprisingly low

The least you might expect to pay for 24 color slides of comparable quality—if the subjects were available from museums and private collections—is $18-$24. Yet, as a subscriber to this new Program, you pay only $12.95 for each complete Album—including slides and illustrated guide book. You may take as few or as many as you like, and may stop whenever you wish.

Your Introductory Album only $1
No obligation to continue

Send no money now. We will ship your introductory Color Slide Album of Impressionist Paintings and enroll you as a trial subscriber. If you are thrilled with the demonstration, send only $1, plus a few cents for tax and shipping. Thereafter, you will be offered a new Album approximately every six weeks at the subscribers' low price of only $12.95. If not delighted, however, you may return the Introductory Album within 15 days, and owe nothing. Mail the attached card today.

If you do not have a projector: here's an unusual opportunity. We can offer you the sensational Kodak Carousel BC 604 Projector supplied with a 300-watt lamp, and 4-inch f 2.8 Ektanar lens. This top-rated projector shows all regular 2" x 2" 35mm. slides up to 1 16-inch thick. It has dependable gravity feed and you have instant access to any one of its 140-slide capacity at any time. List price $139.50—subscribers' low price only $99.50 plus tax (you SAVE $40). Send remittance with trial subscription form. If not completely delighted with the projector, return it in 15 days for full refund.

If Reply Card has been removed, write McGraw-Hill Color Slide Program of Art Enjoyment, Dept. AY-148, 1221 Ave. of the Americas, N.Y., N.Y. 10020.

GOOSE DOWN SOX

Great to wear around home or as bed and sleeping bag sox. Take little space in luggage. Bauer Goose Down quilted in tough nylon taffeta. the old loess steppes left largely by glaciers in Europe, Asia, and America.

Although people with Neanderthal features existed before the Würm Glacial Stage, the last major glaciation of Europe, the classic Neanderthal arose with the first advance of the Würm ice sheets, lasted some 35,000 years, roughly from 70,000 to 35,000 B.C., and vanished abruptly with the first brief warm phase (interstadial) separating the first from the second major advance of the ice. The first human to successfully colonize cold landscapes, Neanderthal was a supercarnivore, killing not only some of the largest and most dangerous ungulates, such as steppe wisent, mammoth, woolly rhino, and horses, but also carnivores, such as wolves and bears.

In cold climates with long winters, living off plant food or off small mammals and birds is not a viable proposition for humans. Not only are edible plants relatively rare in cold-climate floras, but potential foods such as berries drop off in fall or they freeze and thaw and disintegrate. Tubers freeze in the soil and are impossible to excavate or even to find beneath the snow blanket. Most small mammals are hibernating or at least spending much of their time below the snow, and most birds have moved to warm climates. Moreover, to sustain a family on meat, large amounts are needed, and it becomes uneconomical to spend time hunting for small-bodied game. In cold climates, particularly in winter, it is sound economic practice to hunt large-bodied mammals only. (Large herbivorous mammals survive in winter by feeding on dried sedges, grasses, reeds, herbs, twigs, dwarf shrubs, and leaves from trees growing in protected pockets.)

Neanderthal's kill patterns, slanted heavily to large-bodied grazers and carnivores and almost devoid of small game, are beyond comparison with any modern hunting culture. Nor do Neanderthal tools match those of any culture of today, a strong hint that what these early people did will not be found in contemporary societies. This is also implied by evidence that Neanderthal was far more powerful than modern humans. Whereas archeologists can experimentally duplicate the wear pattern on tools such as were used by people from the Upper Paleolithic (the people that followed Neanderthal and are our ancestors), the wear patterns on Neanderthal's tools cannot be duplicated. We do not have the strength to do it. Neanderthal's skeleton reflects a supremely powerful musculature. The joints were massive, even in children, implying an ability for rapid starts and stops. The hands were not only very large but could also be spread wider than ours. The terminal phalanges were large, and the musculature closing the fingers was powerful. The shoulder girdle, besides being massive, was anatomically peculiar in that it was almost simian, implying brachiation (swinging through trees), which is totally incongruous with the open landscapes of the glacial age. Whatever Neanderthal did for a living, there were times when enormous physical strength and violent acceleration and deceleration of the body were essential. As Neanderthals were carnivores capable of killing very large, powerful, and agile mammals, we may look here for a clue to their distinctive anatomy.

How could one safely capture large, well-armed, aggressive, agile, big game? On an open steppe, approaching the game by stalking was hopeless, particularly if snow crunched underfoot. Even if a hunter somehow got close to the animal, how could he kill it quickly enough to prevent being gored and trampled by a wounded beast? Stalking by a single hunter was out of the question. Large, dangerous mammals are not likely to run from carnivores; on the contrary, they are likely to close the distance and attack, and herein lies their vulnerability. If a beast such as a mammoth could be provoked, it would come to the hunter. The task was to kill it without sustaining injury to oneself. A lone hunter could not succeed because the attacking animal gave him its undivided attention, and in facing the hunter it exposed virtually no vulnerable part of its body. The weapons of mammoths, bisons, giant deer, and rhinos were located frontally.

A small group of hunters would have been required to split the attention of the attacking animal, distracting it. Next, in this cooperative venture, one or more of the hunters could quickly maneuver and attack the sides of the animal where vital internal organs were more accessible to inflicted damage. The next logical step would seem to be to throw sharp, pointed spears into the prey, just as was done by our ancestors in the Upper Paleolithic. Their hafted points and spear throwers attest to that. However, Neanderthals left no evidence

of having possessed spears suitable for throwing or of any spear throwers. How then did they kill mammoths, rhinos, and bisons?

The answer requires a brief departure into combat theory. There are two principal means of avoiding damage from an animal's weapon if one cannot parry it. One either stays so far back from the beast that it cannot reach you or one gets in so close that it cannot use its weapons effectively. To escape being hurt by horses that are lined up in a stable, for example, you should either stay so far back that the occasional kicker cannot hit you or else walk along almost brushing tails with your shoulder so that a kicker cannot hurt you. The first means of defense was probably used by our Paleolithic ancestors when confronting the dangerous game that they killed by throwing spears. The second, I suggest, was used by Neanderthal. It is the key to a logical explanation of Neanderthal's morphology, hunting tools, hunting economics, and ultimate demise. I have termed it "close-quarter confrontation hunting."

The advantage offered by close-quarter confrontation hunting with primitive weapons was that it would require few hunters; probably two would do. Extraordinary agility, coupled with high speed and precision of movement, would have been required, however, for one of the hunters to avoid the weapons of an attacking animal. First, he had to evade the attacks, then quickly move in, attach himself to the body of the prey, and have the strength to hold on while an enraged beast tried to fling, shake, and buck him off. With one hunter attached to the prey and holding its attention, the other was free to kill the distracted beast. The hunter should not have been armed with a spear featuring a narrow stone blade, which was a must on throwing spears in order to achieve penetration. Such a blade could shatter on a bone, disarming the hunter. A spear might also completely penetrate the prey and possibly skewer the hunter holding on to the animal on the other side. Also, the wound channel caused by a throwing spear is thin, and so not conducive to quick killing. What was required was the largest possible blade that could be thrust into the prey. Such a blade inflicted a massive wound channel and could strike bones without fracturing. Until the prey weakened and fell, the hunter clinging to it

What your home could have in common with the Met, the Tate, and the Louvre.

Tjelda Michas' *Oriental Poppy*

Beautiful, original works by artists who are represented in the world's great museums and galleries can be yours for very reasonable prices.

We offer original etchings, lithographs, and serigraphs signed by Calder, Chagall, Dali, Miro, Renoir, Vasarely, and other important artists.

Tjelda Michas' vibrant still life, *Oriental Poppy*, is just one of the many fine prints we've recently made available.

Our expert advice and full money-back guarantee are your assurances that the art you buy will have lasting value and beauty.

Send for our colorful, descriptive catalog without obligation.

The Amazing Stirling Cycle **Hot Air Engine**

Heat is the only fuel required!

7¼" x 4"

Silent

Safe

Fully Tested

ALL METAL
SPEEDS TO 1000 RPM
BUILT-IN ALCOHOL BURNER

A marvelous opportunity to acquire an early model Stirling Cycle Engine and acquaint yourself with little known facts about a product of the past that may well hold promise for the future.

The average person has never heard of the Stirling engine, so the sight of one quietly running with heat as its only fuel will at first amaze them and then excite their imagination. This is the first in a family of six different desk-top model hot air engines to be issued during the next three years.

Experimenters • Hobbyists' Power Source
Students • Collectors • Model Engineers

An easily read, lavishly illustrated, 128-page book accompanies each engine or may be purchased separately. This publication, the first of its kind, takes the reader on a 160-year tour through the world of Stirling Cycle Engines. Illustrations include the Stirling, Roper, Heinrici and the amazing new Stirling-powered Ford Torino!

Solar Engines • 4020 East McDowell Road, Phoenix, AZ 85008 U.S.A. (602) 274-3541

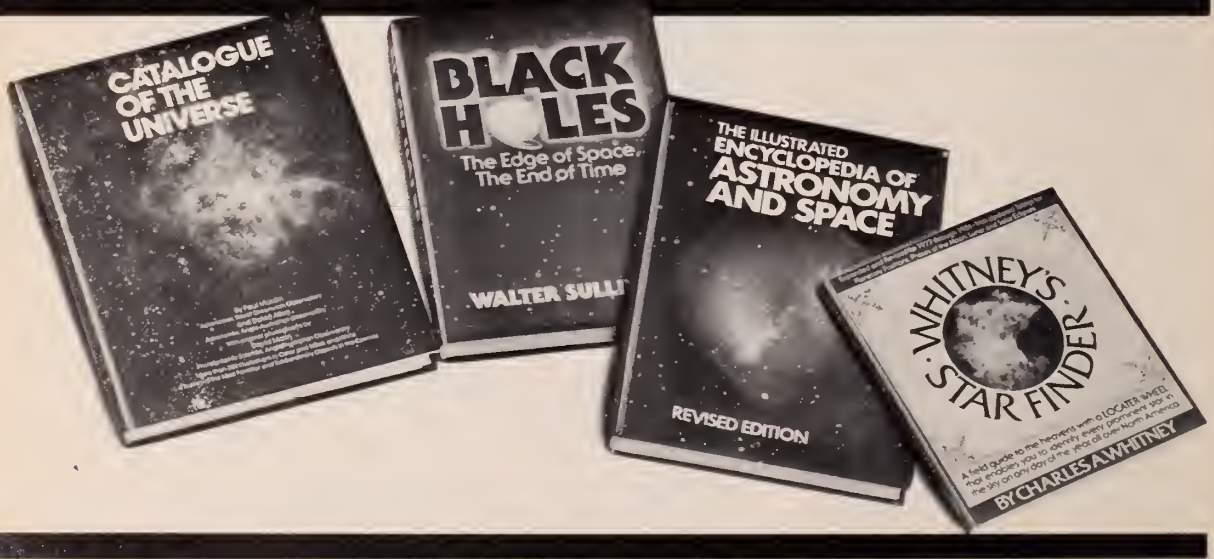
5 good reasons for joining the
Natural Science Book Club



1. Van Nostrand's Scientific Encyclopedia

Edited by Douglas M. Considine. Nearly 200 experts have contributed to this thoroughly revised and greatly expanded fifth edition of the most authoritative single-volume source of scientific knowledge ever assembled. Enormous 9¼″ × 12″ volume contains 2.2 million words, 2382 pages, 2500 photographs, drawings, and charts, and 500 tables. 7200 articles cover everything from the earth and space sciences to energy technology, from the life sciences to mathematics, from the information sciences to physics and chemistry. ". . . an amazing book . . . for both the general and scientific reader."—*The New York Times.* **Publishers' Price $69.50**

2. Archaeology Library

Two extensively illustrated volumes provide a panoramic overview of ancient cultures. ***The Cambridge Encyclopedia of Archaeology***— an oversized reference with more than 400 photos, drawings, maps, and plans. Includes writings by 55 experts. ***Discovery of Lost Worlds***—the major archaeological finds of the past 300 years recreated in the writings of well-known scholars. Beautifully illustrated. **Publishers' Price $69.90**

3. Basic Astronomy Library

Four books that will provide you with a basic, well-rounded library. Start with ***Catalogue of the Universe.*** Three-volumes-in-one: an atlas, encyclopedia and book of descriptive astronomy. Surveys over 220 astronomical objects. More than 300 photographs. ***Black Holes: The Edge of Space, The End of Time. Whitney's Star Finder*** enables you to identify every major star in the sky over North America. ***The Illustrated Encyclopedia of Astronomy and Space*** contains over 1000 entries and 150 photographs and illustrations. **Publishers' Price $60.80**

4. Ancient Civilizations

A four-volume set including ***The Archaeology of Greece: An Introduction.*** A remarkable historical and artistic account of the splendor of ancient Greece. 334 black and white photographs. Plus, 8 pages of color plates. ***Ancient Egypt***—a fascinating survey of Egyptian civilization, contains 125 photographs. ***Stonehenge and Its Mysteries***—over 200 maps, diagrams and photographs. ***The Maya.*** The extraordinary Mayan civilization. Includes all the latest discoveries. Over 140 illustrations. **Publishers' Price $81.80**

5. Natural History Library

A carefully selected three-volume set consisting of ***Deadly Beautiful: The World's Most Poisonous Plants and Animals.*** A breathtaking survey of toxic reptiles, insects, plants, fruit and fish. Illustrated with 250 photographs, many in color. ***The Spotter's Guides***—a set of six colorful field guides: Birds; Trees; Wild Flowers; Rocks and Minerals; Shells; The Night Sky; ***Fossils of All Ages***—a superb collection of photographs reveals the history of fossils, how they are formed, what they consist of and the rules that dictate their shape and symmetry. **Publishers' Price $76.65**

Take either Van Nostrand's Scientific Encyclopedia or any one of these other 4 outstanding Sets for only $2.97

(values to $81.80)

if you will join now for a trial period and agree to take 3 more books—at handsome discounts—over the next 12 months.

As a member, you'll be kept informed of the most interesting, most important science books being published. You'll get to choose from a dazzling array of books—from fascinating accounts of the discovery of lost civilizations to speculations on the origin of our universe, from beautifully illustrated books on the world of nature to stimulating books on where man came from and where he is going. Join now and see for yourself.

MEMBERSHIP BENEFITS • In addition to getting either Van Nostrand's Scientific Encyclopedia or any one of these 4 outstanding Libraries for only $2.97 when you join, you keep saving substantially on the books you buy. • Also, you will immediately become eligible to participate in our Bonus Book plan, with savings of at least 70% off the publishers' prices. • At 3-4 week intervals, (16 times per year) you will receive the Book Club News, describing the coming Main Selection and Alternate Selections, together with a dated reply card. • If you want the Main Selection do nothing and it will be mailed to you automatically. • If you prefer another selection, or no book at all, simply indicate your choice on the card, and return it by the date specified. • You will have at least 10 days to decide. If, because of late mail delivery of the News, you should receive a book you do not want, we guarantee return postage.

Natural Science Book Club 4-AK8
Riverside, N.J. 08075

Please accept my application for trial membership and send me either Van Nostrand's Scientific Encyclopedia or any one of the four libraries, billing me only $2.97. I agree to purchase at least three additional Selections or Alternates over the next 12 months. Savings range up to 30% and occasionally even more. My membership is cancelable any time after I buy these three books. A shipping and handling charge is added to all shipments.

Check which one you want:
- ☐ Van Nostrand's Scientific Encyclopedia (00470-3).
- ☐ Archaeology Library-A (10130)
- ☐ Ancient Civilizations-A (10106)
- ☐ Natural History Library-A (10111)
- ☐ Basic Astronomy Library-E (10150)

No-Risk Guarantee: If you are not satisfied—for any reason—you may return your introductory books within 10 days and your membership will be canceled and you will owe nothing.

(Offer good in Continental U.S. and Canada only. Prices slightly higher in Canada.)

needed the endurance to hold on no matter how violent the motions of the prey. To loosen his hold would have jeopardized his life, as well as that of his companion or companions.

If great strength, agility, and precision and speed of bodily movements were required for such a hunting technique, those parts of the brain controlling motor functions in the hunter had to be greatly developed. Neanderthal possessed a massive cerebellum and motor cortex compared to modern humans. This pulled the brain case rearward, creating an occiput that reached farther rearward than in modern humans, explaining, in part, the large, long, low brain case and bun-shaped occiput of the Neanderthals. Experimental evidence shows that, phenotypically, brain size is a function of the diversity of well-mastered motor patterns, as well as a result of good nutrition. The build and condition of the bones of Neanderthals speak for exceedingly good nutrition and a great deal of exercise. (This also applies to females, who were, as in modern humans, somewhat smaller than males. They, too, were apparently well-muscled.) I submit that the brain size and shape of these people fit with the demands of close-quarter confrontation hunting.

Given all of the preceding conjectures, Neanderthal hunters would have done best to focus on large mammals with long hair, allowing for a solid handgrip. Mammoths, woolly rhinos, steppe wisent, and horses were such animals. Compared with us, Neanderthal's hand not only covered a great span but the long, broad-tipped fingers offered a greater surface area with which to hold hair. Neanderthal man's powerful adductor muscles, great ability to spread his fingers, and big, fleshy fingertips now have a logical explanation. So do his massive arms and "brachiating" shoulder girdle.

Examination of kill patterns shows that Neanderthals rarely killed aurochs (*Bos primigenius*), the ancestor of domestic cattle, and moose. Cattle have a short-haired smooth surface, difficult to grasp and to hold on to. Also, their ability to spin around in a tiny space, buck effectively, and attack can be attested to by anybody visiting a rodeo. Moose hair breaks or pulls out. But both moose and cattle could be killed by hunters using throwing spears, and Upper Paleolithic hunters killed these two species regularly. Thus the paucity of cattle and moose kills in the Mousterian (Neanderthal) layers in Ukrainian and Russian sites may be explained as a consequence of the postulated hunting methods of Neanderthal. There is no reason to suspect that aurochs and moose were rare in Neanderthal's time and common in the Upper Paleolithic.

For killing rapidly at close quarters, as indicated earlier, a thin-bladed throwing spear may not only be ineffective but also dangerous. Ideally, a hafted blade on a thrusting spear should be as wide as the strength of the hunter permits him to thrust it through a thick hide, muscles, and fat. The boar spear from medieval Europe shows the solution to the problem of quickly killing a big, violent, tough creature. The blade is thick, some three inches across the edge, with a rounded point—very similar to the big, thick, massive Mousterian points. We know that Neanderthals worked in wood, sufficient reason for us to suspect that they could make handmade thrusting spears. Refined workmanship would add nothing to the effectiveness of the blade. We also know that Neanderthal people made hand axes, which they embedded partially into mastic, a material made from clay and tree resins. Without the mastic cap, the hand axes would, of course, have cut the hand. These axes must have been used with great force. Such an ax could be used to crush the lumbar vertebrae of a steppe wisent or horse with one blow, slash open a chest cavity, or cut the tendon on a hindleg of the prey. Thus Neanderthal's weapons, morphology, and kill patterns fall logically within a close-quarter confrontation hunting strategy.

The dentition of Neanderthal people and their peculiar hearths are linked to some consequence of killing game with primitive weapons in cold climates. Large mammals killed in winter had to be dismembered quickly before they froze. After the cut meat froze, the chunks had to be carried to a convenient shelter. The chunks of frozen meat were most likely thawed and roasted by placing them directly into a bed of coals in a large hearth. This had several consequences. First, the meat came in contact with ashes, sand, and bone grit. Eating such meat would have caused tooth abrasion. The open-rooted and possibly continually growing cheek teeth of Neanderthal are the logical correlate to such abrasive food. Singed and charred meat had to be forcefully removed from layers that were still raw and frozen. This meant that either the meat was somehow cut off or that the person bit directly into the joint and worried off a piece of meat. The latter requires powerful incisors and a sawing motion of the jaw amenable to severing tough, fibrous meat. The jaw anatomy indicates that a backward and forward movement of the jaw existed—admirably suited for grinding incisors against one another. Thus Neanderthal's projecting jaws and large incisors would function admirably for working free amounts of tough meat from joints. Such use of the front teeth should not only lead to heavy wear but also to noticeable wear on the front of the incisors. The fossil evidence verifies this.

Another consequence of bringing crudely severed joints to a fire was an accumulation of bones. To leave bones about a campsite would attract bears or other carnivores. Burning all bones not only removed the attraction, but would also result in large hearths filled with bone ash so typical of Neanderthal hearths.

To understand their demise, one must go a little further in unraveling the way Neanderthals lived. There is no evidence for Neanderthals, as there is for Upper Paleolithic people, having killed much in excess and preserved the surplus meat. Neanderthals probably lived from kill to kill. In winter, without a reliable surplus of stored food to fall back on, they could not afford to stay where the occurrence of game was unpredictable. They could only survive in winter by living in areas with a high density and diversity of large mammals. They must, therefore, have been confined to the most productive localities. This implies that under comparable conditions Neanderthals would have had a more restricted geographical distribution than Upper Paleolithic people.

Further, without the practice of storing surplus food or boiling bones to extract the protein, Neanderthals were less likely to be as efficient in utilizing carcasses as were people from the Upper Paleolithic. Since there is no evidence for sophisticated clothing or shelters, we may assume that Neanderthal people—like people living in the high Andes—kept warm by eating more food. Compared with the Upper Paleolithic people, Neanderthal people would have had to hunt more. They must have been very sen-

HOW TO FOIL A CAR THIEF

A FEW SIMPLE PRECAUTIONS CAN REDUCE THE RISK OF THEFT

The numbers are staggering. Every 37 seconds or so a car is stolen somewhere in the U.S. That adds up to almost 800,000 cars a year. But you can do something to keep your car from becoming a statistic. Start by avoiding these four common parking mistakes.

The "Just for a Minute" Syndrome. When you leave your car, even if it's "just for a minute," lock all of the doors and take your keys. In fact, about one of every five cars stolen was left unattended with keys in the ignition. Keep driver's license and vehicle registration cards in your wallet or purse. If a car thief finds these documents in the vehicle's glove box, he can impersonate you if stopped by the police.

The Isolated Location. It's safest to park in a locked garage, but if you can't, don't leave your car in a dark, out-of-the-way spot. Instead, try to park on a busy, well-lighted street. Thieves shy away from tampering with a car if there's a high risk of being spotted.

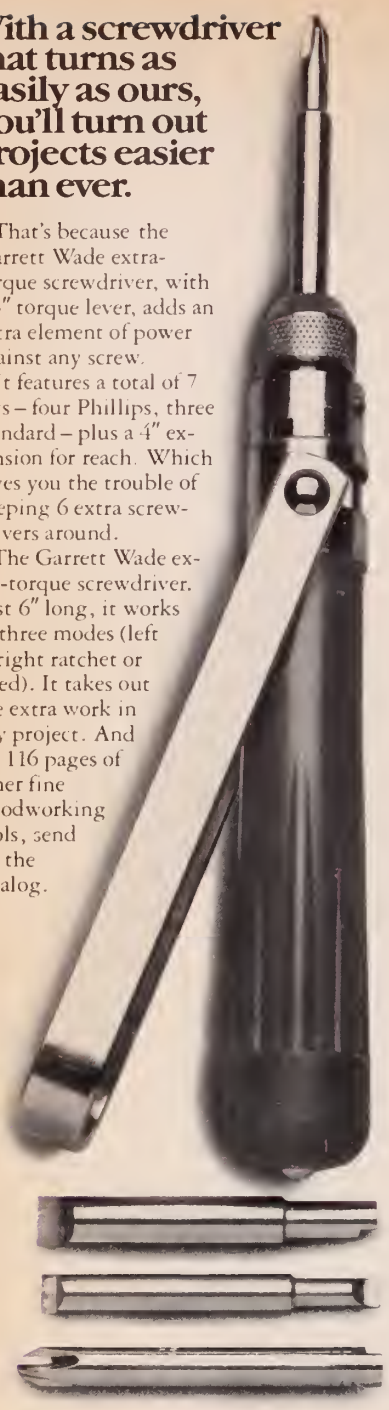
The Display Case. There's nothing more inviting to a thief than expensive items lying in your car, in plain sight. If you lock these items in the trunk or glove box, there's less incentive for a thief to break in. Also, when you park in a commercial lot or garage, be cautious. Lock your valuables in the trunk, and leave only the ignition key with the attendant.

The Space at the End of the Block. In recent years, professional car-theft operations have become an increasing problem. Unlike amateurs, the professionals are not easily deterred. Cars parked at the end of a block are easy targets for the professional thief with a tow truck. So, it's best to park in the middle of the block. Be sure to turn your steering wheel sharply to one side or the other. That will lock the steering column and prevent the car from being towed from the rear.

Unfortunately, there's no such thing as a "theft-proof" car. But at General Motors, we're equipping every car we build with anti-theft features. We want to help you make it as difficult as possible for any thief—amateur or professional—to steal your car.

This advertisement is part of our continuing effort to give customers useful information about their cars and trucks and the company that builds them.

General Motors



People building transportation to serve people

With a screwdriver that turns as easily as ours, you'll turn out projects easier than ever.

That's because the Garrett Wade extra-torque screwdriver, with a 3" torque lever, adds an extra element of power against any screw.

It features a total of 7 bits – four Phillips, three standard – plus a 4" extension for reach. Which saves you the trouble of keeping 6 extra screwdrivers around.

The Garrett Wade extra-torque screwdriver. Just 6" long, it works in three modes (left or right ratchet or fixed). It takes out the extra work in any project. And for 116 pages of other fine woodworking tools, send for the catalog.

Offer expires September 15, 1981

sitive to changes in game densities. This predicts that compared with the Upper Paleolithic people, Neanderthals lived at lower densities, rarely formed large groups, and only exceptionally lived in communal dwellings. This is supported in part by the Russian archeological record; the camps of Neanderthal man are about one-fifth as frequent as those from the Upper Paleolithic, although the latter period was the shorter.

The first retreat of the Würm ice was followed by a brief but very warm interstadial period. (The extent of glacial melting is attested by the fact that ocean shorelines were much higher 35,000 years ago than they are today.) Forests rapidly replaced loess steppes and grasslands. This would have caused the once large herds of grazers to become depleted and fragmented. As the grazers with shaggy coats grew scarce, the geographical range of Neanderthal people must have shrunk rapidly. The last of the Neanderthals exhibited reduced body growth, a sign of inadequate nutrition. They probably went extinct in a short period.

A glaciation later, the same fate nearly befell the culturally and technologically sophisticated Upper Paleolithic people. They came close to extinction during the terrible Mesolithic period that followed the glaciation. Population size in Europe shrank, people were poorly grown, diseased, and short-lived. Homicide and cannibalism were common. However, the technology changed, new ecosytems such as the marine shores and freshwater deltas were exploited, and our kind survived. Neanderthal people, by comparison, were more biologically, and less culturally, adapted to their role in glacial landscapes. They were, therefore, not primitive humans. On the contrary, Neanderthal was more specialized biologically for the role of a superpredator than we are, and consequently is the most specialized human from the past. It was probably only after the Neanderthals' extinction that modern people could colonize the land they once roamed over, for they must have been fighters of stunning abilities, for whom Upper Paleolithic people were no match.

Valerius Geist is associate dean in the Faculty of Environmental Design of the University of Calgary. He is an authority on the ecology of ungulates, particularly goats and deer.

For centuries man feared it, made sacrifices to it, wailed over it. Now we run to greet it. You are extended a unique invitation to witness one of nature's most awesome spectacles, a total eclipse of the sun. On July 31, 1981 the British cruise ship, m.s. Coral Princess will be positioned 1000 miles off the coast of Japan to rendezvous with eclipse totality.

The ORIENT ECLIPSE CRUISE and expedition is the sequel to the six previous historic VOYAGE TO DARKNESS eclipse expeditions which successfully intercepted totality off the coasts of Nova Scotia, Africa, the Caribbean, in the Pacific and at Montana's Big Sky eclipse expedition.

The ORIENT ECLIPSE CRUISE adventure offers a distinguished staff of shipboard lecturers (including meteorologist Dr. Edward M. Brooks) scientific, cultural and educational programs, and tours of Japan, Hong Kong, Macau and China.

Join us as we probe earth, sea and space for yet another exciting and memorable cosmic adventure as we sail into totality and beyond.

THE NEW SCHOOL IS ANTI-FOSSIL.

We have nothing against your Jurassic, your Triassic, or your Upper or Lower Cretaceous models. The kind of fossilization we hate to see is the sort that takes place in *Homo sapiens,* usually from the neck up.

As any dinosaur will tell you, being a fossil is no fun. And, happily, it's a fate easily avoided. At The New School, we ward off mental petrification with more than 1700 courses this spring, everything from astronomy to yoga: courses in social sciences, pure and applied sciences, humanities, languages, creative and performing arts, business and finance, and, through Parsons School of Design, art and design.

Fossils belong in museums. Anti-fossils belong at The New School. Mail the coupon below, or call

(212) 582-5555

24 hours a day, 7 days a week. Either way gets you a copy of our spring semester bulletin.

British Museum (Natural History)

A century ago, a new museum was built to house the British Museum's crowded, cobwebbed natural history collections. Since then, the London museum has become one of the world's great scientific institutions

by William E. Swinton
photographs by Lee Boltin

This year, one of the world's great scientific institutions, London's Natural History Museum, is celebrating one hundred years as a separate museum. The British Museum (Natural History), as it is officially called, is best known for its role in education and the richness of its exhibitions, but as is true of so many fine museums, scientific research constitutes the bulk of the work carried out within its walls and on the expeditions and fieldwork it sponsors. For both of these functions—the educational and the scientific—the men and women who work in the museum today, and the visitors who throng its impressive halls, owe a tremendous debt to the men who brought the museum to life one hundred years ago.

For more than a century the Natural History Museum had been an integral part of the British Museum in Bloomsbury, one and a half miles north of Charing Cross. By the middle of the nineteenth century, however, the growing collections of minerals, plants, fishes, fossils, and other treasures had put so much pressure on the limited space available in Bloomsbury that the decision was reached to house the natural history collections separately. From 1880 to 1883 the Natural History Museum moved from its crowded quarters in the British Museum into a new home, complete with towers, spires, and navelike central hall, in South Kensington, three and a half miles west of Charing Cross.

The history of both the "new" Natural History Museum and its parent, the British Museum, began in 1753 with a single Act of Parliament. The act authorized the purchase of the collections of the distinguished and wealthy physician Sir Hans Sloane (1660–1753), and thus founded the British Museum. President of the Royal Society, president of the College of Physicians, physician general of the army, and physician to the queen, Sloane was also a botanist and avid collector. Montagu House, his home in Bloomsbury, became the new British Museum and housed the natural history collections until shortage of space necessitated the move to South Kensington.

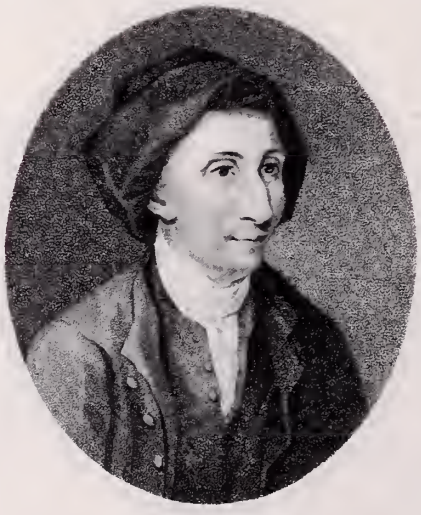
Sloane was a member of Britain's oldest natural history society, the Temple Coffee House Botanic Club, founded in 1689. The members of this organization approached their subject with boundless enthusiasm, combing the local countryside for plants and animals and meeting incoming ships to beg the sailors and passengers for exotic specimens. The collections that resulted were often heterogeneous and of little true scientific value. Sloane's collections were in better shape than most, but since no arrangements had been made for their preservation, many of the specimens perished during the museum's early days in Bloomsbury. Nonetheless, natural history specimens were plentifully represented in the new museum.

Hans Sloane
The Bettmann Archive

Identification of specimens in the collections presented a great challenge, however. Carolus Linnaeus, the great eighteenth-century Swedish botanist and physician, had met Sloane on a visit to London in 1736 and been much impressed with his collections. By helpful coincidence, 1753, the year that the British Museum was born, was also the year that Linnaeus published his *Species Plantarum*. In 1758, his *Systema Naturae*, regarded as the basis of modern zoological nomenclature, appeared in its tenth edition. In Europe at least, collected specimens could now be named in an understandable manner, an advance that did much to promote scientific and medical understanding.

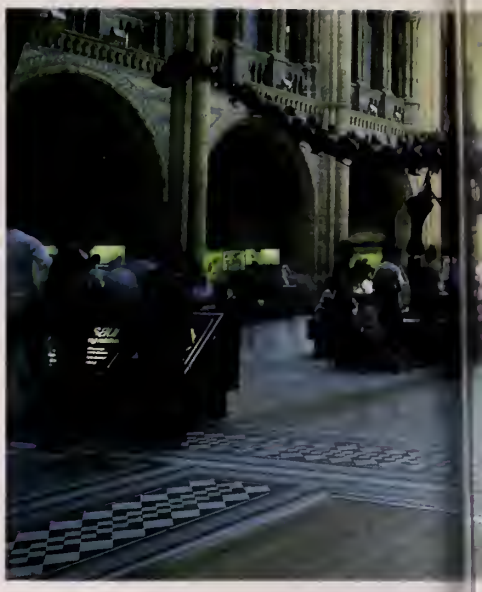
The museum's early vicissitudes are well recorded. It was short of money, short of space, and short of staff. What staff the museum did have was usually volunteer and often included a large proportion of nonpracticing physicians—not surprising in a time when a medical degree was largely a degree in natural history. More than a century after the founding of the British Mu-

Carolus Linnaeus
The Bettmann Archive



seum, Prime Minister Gladstone, during an escorted tour of the museum, was astonished to hear that people were actually paid to work there.

Not everyone appreciated the visual encyclopedia beginning to take shape in Bloomsbury. In William Makepeace Thackeray's *The Virginians*, one character expresses the critical opinion that some Londoners held of the new museum: "By George, I don't know where the town's running. There's Montagu House made into a confounded Don Saltero's Museum, with books and stuffed birds and rhinoceroses." (The catalog of Don Saltero's Museum, a once popular London museum, is now owned by the British Museum.)



The new museum was, indeed, no bonanza for the public. Only small parties of "respectable" people were allowed in for guided tours that lasted half an hour. Yet around the country, more and more respectable people, especially the landed classes, were becoming interested in gardens and horticulture and in the frequently lavish books being published on these subjects. Similarly, as the museum's collections grew, so did the number of people who, influenced by the increasingly popular fields of archeology and the natural sciences, wanted to see for themselves the bounty of nature housed in the museum.

The names of the early keepers of the Natural History Department in Bloomsbury may mean little today, but they belong to men who were important in the formation of the museum and in the scientific world of the time. For example, the keeper from 1765 to 1773 was Matthew Maty, a Dutch physician from Leiden, who as a fellow of the Royal Society and, later, foreign secretary of that distinguished body was scientifically influential. He apparently had an aversion to museum visitors and doled out passes reluctantly. His successor was the great botanist Daniel Solander, a favorite student of Linnaeus. Coming from Sweden, Solander played an important part in introducing the Linnaean system to Britain. Learned and urbane, he traveled around the world with Capt. James Cook and Sir Joseph Banks, botanist and patron of the sciences. Solander's influence on the museum was great, and his participation in the intellectual activities of the time, including membership in the Royal Society and the Lunar Society, enhanced the prestige of the museum and brought additions to its collections.

The last of the early keepers of the Natural History Department, E.W. Gray, saw the museum through the change of centuries. As it moved into a wonderful era of new knowledge, the museum struggled to keep its collections in some semblance of order. The department was expanded and given a new name: Department of Natural History and Modern Curiosities. Its first keeper, George Shaw, was given no money to go with this long title, however, and so, he "wrote for booksellers." Accounts of the collections report that owing to inevitable neglect, "the basements of Bloomsbury resemble the catacombs at Palermo, where one is opened every day of the year, merely to deposit fresh subjects for decay." Some of the more

Matthew Maty
The Grenger Collection

decayed specimens in the Sloane collection had to be burned.

But then the intellectual spring arrived. In 1807 the Geological Society of London was founded, and in 1826 the Zoological Society of London. John James Audubon's *Birds of America* was published in London in 1827, and Charles Lyell's *Principles of Geology* appeared in 1830, the same year the Royal Geographical Society was founded. The next year, at York in the northeast of England, the British Association for the Advancement of Science was inaugurated, and in the city of Plymouth in the southwest, a young naturalist named Charles Darwin stepped on board a little ship called the *Beagle*. In 1833, the Royal Entomological Society opened its doors, followed by the Botanical Society of the British Isles in 1836. Britain's scientific community was never to be the same. Specimen logged and cobwebbed as it was, the British Museum enjoyed a growing reputation during this period. In 1818, William MacGillivray, age twenty-three, walked the eight hundred miles from Aberdeen, Scotland, to London in six weeks just to see the museum's natural history collections. Apparently satisfied with his visit, he returned by boat to Aberdeen, where he became professor of natural history. Charles Darwin, writing to his sister in 1833 about the wonders of South America, claimed that if he had not been able to undertake his travels, he "would be a ghost and haunt the British Museum."

Throughout the first half of the nineteenth century, the museum grew

The Irish wolfhound, seemingly alert to the activity around it, is proof of the department's skill; it too is part of the new exhibit. Left: I.W.B. Nye of the Department of Entomology compares a male specimen of* Thysania agrippina, *the world's largest moth, with the earliest illustration of the species, in P. Cramer's* Uitlandsche Kapellen, *1776.*

and changed: collections merged, keepers retired or transferred to new departments, new keepers joined the staff. In 1853, the Zoological Society of London decided to give up its own museum and presented its type specimens to the British Museum. The whole structure of the Natural History Department changed in 1856, so that it became virtually a separate museum within the museum. In May of 1856, when Richard Owen was appointed the department's first superintendent, great changes were imminent.

Richard Owen (1804–92) was perhaps the greatest anatomist of Victorian times, despite an implacable opposition to Darwin's theory of evolution by natural selection. A physician and fellow of the Royal Society, he had been in charge of the John Hunter collection and others at the Royal College of Surgeons, where he was professor of comparative anatomy. Also a paleontologist, he came to the Natural History Department as a professional, and he realized that to make order out of chaos, he would have to find more space. Owen was not the first to come to this conclusion, but he pressed the matter relentlessly, and since there was no room to expand the facilities in Bloomsbury, he sought a separate site at South Kensington. His first proposal was turned down by the government in 1860 on financial grounds, but in 1862 twelve acres of the 1862 International Exhibition by the Cromwell Road were acquired for the purpose of establishing a new home for the Department of Natural History.

The first architect chosen to design the new museum building was Capt. Francis Fowke of the Royal Engineers. The museum trustees rejected his plans, however, and in 1865 he died while amending them. Alfred Waterhouse was approached in 1866 and eventually agreed to undertake the demanding task, but it was 1871 before his plans were approved by the trustees and 1873 before construction began. The new building was more or less ready by 1880, and in April of 1881, the museum was officially in business.

Most large Victorian buildings were either cathedrals or railway stations, and the Romanesque-inspired Natural History Museum in South Kensington, with its great hall and stained-glass windows in its side galleries, conformed to these models. The building's unusual façade was encased in terra cotta, a kiln-burned clay so fine that the grime of London could not infiltrate it. The upper part of the east wing was decorated with representations of animals of the past, that of the west wing with modern organisms—a separation of fossil and living organisms that reflected Owen's original plan for the public galleries. Man was perched at the peak of the roof above the entrance. Unfortunately, the grand design provided no space for a working staff or for specimens preserved in spirits; no room for large mammals such as whales, except in the entrance hall; and almost no space for a library.

Filling the new space with the old collections took nearly three years, but Owen did not stay to see it all. In the fall of 1883, he wrote in his diary:

> With this year end my official relations with the national collections of natural history, the several collections,—Zoology, Geology, Fossils, Minerals, Plants,—being arranged and displayed in their respective galleries. I felt that I could now "depart in peace" for mine eyes had seen *their* salvation.

On his retirement from the museum on January 5, 1884, Queen Victoria made Owen, then in his eightieth year, knight commander of the Bath.

Owen was succeeded at the Natural History Museum by a true museum man, William Henry Flower. Qualified medically in London's University College Hospital, Flower was a medalist in physiology and zoology, had served as a medical officer in the Crimea, and was the first of the museum's leaders to have extensive museum training. Curator for a time of a small medical museum, in 1861 he became curator of the Hunterian Museum at the Royal College of Surgeons. In his twenty-three years in this post, he reorganized the collections, increased the displays, and wrote on mammalian anatomy. In 1870 he succeeded Thomas Huxley as professor of comparative anatomy and physiology at the college, and in 1879 he was appointed president of the Zoological So-

The Natural History Museum's rare book collection includes, right, a first edition of Linnaeus's Systema Naturae; *sketches and drawings by Sydney Parkinson, who accompanied Captain Cook on his first voyage; and a handwriting collection used to verify signatures. In recent years, the museum has opened several imaginative exhibits. The bright, explicit graphics in Human Biology, below, were controversial when this exhibit opened. The modern design of Introducing Ecology, below right, provides a sharp contrast to the museum's architectural style.*

ciety of London, a position he held for twenty years.

Thus, when Flower came to the museum in 1884, he was uniquely qualified for a unique post, the first directorship of the new museum. Almost at once he brought a new sense of purpose to the task, understanding that he had in his hands a wonderful instrument of public instruction and inspiration. He set about creating exhibitions that would teach rather than simply display and devised the "Index Museum," a series of exhibits in the central hall that illustrated comparative anatomy.

With its growing role in education and a policy of free admission, the museum took on a public look. The realization that without an audience to charm, influence, and inform, the museum was largely mute had been a long time coming. The possibilities for conducting research in the museum, never overlooked by Flower, were increased by the favorable public reaction and by the gifts of collections. Flower became active in spreading his new gospel of museums, using his presidency of the Zoological Society and of sections of the British Association to reach a wider and more influential audience. He published on museums as well as on mammals and supported the formation in 1889 of the Museums Association, which has since reached across the world with its journal and professional examinations.

Through the end of the nineteenth century and the beginning of the twentieth, the museum prospered as its departmental structure became increasingly well defined. During this

Daniel Solander
The Granger Collection

period the keepers of the museum were men of great distinction, all of them fellows of the Royal Society. Their participation in influential organizations brought new collections and new forms of technology to the museum and helped attract ambitious young people to the careers that the museum could now offer. The prestigious collections were continually outgrowing the study rooms, storerooms, and narrow galleries allocated to them. In fact, several collections, including the diaries, notebooks, and marine deposits from famous oceanographer Sir John Murray's round the world voyage aboard HMS *Challenger* (1872–76), were set up in small, separate buildings of their own.

The growth of the collections called for skilled curators, and joining the scientific staff became a more difficult undertaking. Applicants were required to have a good degree in the appropriate subject and had to be nominated for entry by one of the museum's principal trustees. Only after passing an interview were they permitted to sit a civil service examination. While this system more or less assured that staff members understood the subject on which they were to work, it provided no guarantee of curatorial interest or ability.

The collecting instinct, a crucial element in the making of an able curator, is rooted deep in the human psyche. In *The Little Universe of Man* (1978), biologist Cyril Dean Darlington discusses this instinct and its proper role in modern science:

> The instinct for collecting, which began as in other animals as an adaptive property, could always in man spread beyond reason; it could become a hoarding mania. But in its normal form it provides a means of livelihood at the hunting and collecting stage of human evolution. It is then attached to a variety of rational aptitudes, above all in observing, classifying, and naming plants, animals, and minerals, skills diversely displayed by primitive peoples. These skills with an instinctive beginning were the foundation of most of the civilized arts and sciences. Attached to other skills in advanced societies they promote the formation of museums and libraries; detached, they lead to acquisition and classification by eccentric individuals, often without any purpose or value at all.

Darlington's remarks point up another problem all museums face: what to do with growing and aging collections. At the turn of the century the Natural History Museum still had collections of Charles Darwin, Alfred Wallace, John Gould, and others—benefactors, collectors, scientists, and eccentrics. What should be done with them? Should they be treated as historical relics, too precious to handle, or used, carefully, as steppingstones to more modern knowledge? The wall cases in the South Kensington museum, deep, dark, and high, were obviously not made for human faculties of perception, and the table cases, suitable enough for exhibiting relatively small objects and storing others, often served as barriers to divide the staff workrooms from the wandering public. To relieve part of the problem, the museum soon extended a warmer welcome to the public.

In July 1913, some thirty years after the new Natural History Museum was furnished, a pamphlet entitled *The Public Utility of Museums* was published. Intended to "call the attention of all Local Authorities to the desirability of the Public having the

Richard Owen
The Granger Collection

William Henry Flower
The Granger Collection

means of obtaining information at all Museums, Gardens, and Galleries," this tract included among other items a number of announcements from the great London museums. One was of particular interest as it noted the appointment of J.H. Leonard, B.Sc., "to conduct parties of Visitors round the Collections," adding that "NO CHARGE is made for this service and no gratuities are to be offered." Mr. Leonard appeared at the museum at noon and at 3:00 P.M., six days a week, with a demanding program that covered as many as seventeen galleries, pavilions, and corridors. Furthermore, special groups could obtain Mr. Leonard's services at other hours, again without charge or gratuity. Leonard and his successors served as guides, philosophers, and often friends to the many individuals who followed them through the museum, week after week, year after year. The museum inspired many people, and for some the tours became a way of life.

In 1931, the Natural History Museum celebrated its first fifty years. By then, museum visitors wanted souvenirs, so new guides were produced. During this period, such figures as King George and Queen Mary; King Alfonso of Spain; Field Marshall Jan Christian Smuts, prime minister of South Africa; and many others visited the museum, and the Staff Association gave monthly tea parties.

At the time of its fiftieth anniversary, the museum addressed itself to matters referred to in a four-page report by the Royal Commission on National Museums and Galleries. The report concluded that the museum needed more staff, better accommodations, and money to play a more active part in expeditions abroad.

Also at this time, under director Tate Regan, an ichthyologist, the museum put together *A Short History of the Collections*, a review of its collections and the departments that contained them. The studies required for this undertaking revealed that through the years some items in the museum's collections had been lost forever. For example, little that was truly ancient in the mammal collection could be identified, two exceptions being the still intact forehead of a West African dwarf buffalo first described in a scientific publication in 1686, and the skeleton of a young chimpanzee described in 1699.

The next decade was a troubled one for the world and the museum. During the Second World War, the museum was struck by bombs many times, suffering fire and water damage. Yet some of the more important specimens, such as an *Archaeopteryx* fossil, fared better, sandbagged and cellared in South Kensington, than those that had been transferred to the cold and damp of stately homes and abandoned slate mines.

The postwar years saw an expansion and reorganization of the staff along civil service lines. Publications began to flow again, and in time galleries were restored and reshaped. In the last decade, several structural changes have been made, including the much-needed addition of a new paleontological wing at the east end of the museum. The whole concept of the museum has been altered, largely by those within the institution. It remains a great source of scientific knowledge through collecting, research, and publication, but it now welcomes the public as never before, with new and imaginative exhibits, accompanied by books that enlarge on the ideas presented. The past three years alone have seen the opening of four exhibits: Human Biology, Introducing Ecology, Dinosaurs and Their Living Relatives, and Man's Place in Evolution. And one of the main events in this year's centenary celebrations will be the opening of yet another, Origin of Species. All of these new exhibits incorporate contemporary visual and mechanical aids, including computers, to emphasize more effectively the diversity of the natural world and the underlying principles of biology.

Alfred Waterhouse
The Granger Collection

This guelder-rose, or snowball (Viburnum opulus), *is part of a collection of dried, pressed specimens made by the young Linnaeus when he was curator of the garden of Dutch merchant George Clifford.*

Old and gray, like many of its friends at home and abroad, what memories the Natural History Museum evokes. The list of distinguished scientists who have walked its galleries is long: Teilhard de Chardin, French paleontologist and philosopher; Robert Broom, anthropological wizard of South Africa; the Leakeys, always bursting with enthusiasm over new and newer finds of the remains of early apes and humans in East Africa; Henry Fairfield Osborn, curator of vertebrate paleontology and president (1908–35) of the American Museum of Natural History; George Gaylord Simpson, evolutionist and paleontologist; and hosts of other friends who came from museums of renown around the world and found themselves much at home in the Cromwell Road.

Returning from expeditions to Africa, India, Madagascar, Australia, the Arctic, and Antarctica, travelers can sometimes catch, as their planes are on the approach to London Airport early in the morning, a glimpse of the museum's arched roofs, shining tiles, and pointed towers, all set in the sunken garden of the Cromwell Road. They can sigh with relief: It is still there, and they are home. Long may the museum remain a home for the traveler whose name is renowned, a place of resort for the thousands who have yet to make their scientific name, and a place of wonder for all. □

The Acadians of Belle-Ile-en-Mer

Exiled from bountiful lands in Canada, these eighteenth-century refugees with New World notions reluctantly settled on a rocky French island

by Naomi E.S. Griffiths

photographs by Henri Bancaud

The inhabitants of Belle-Ile-en-Mer trace their ancestry, in part, to settlers from what is now Nova Scotia and New Brunswick.

New York Public Library

Belle-Ile-en-Mer lies in the Bay of Biscay, some fifteen miles off the southern coast of Brittany. Seven miles long and five and one-half miles across at its widest point, the island runs from northwest to southeast across the Gulf of Morbihan, acting to protect the mainland port of Quiberon. Its wind-swept cliffs, sheltered harbors, and scattered sandy bays, all free of industrial development, have made Belle-Ile a tourist attraction. But there is more to the island than the wild beauty of Apothecary's Cave and the tranquillity of the fishing hamlet of Locmaria. There is also a complex history.

For centuries Belle-Ile was a haven for pirates. Over many decades, from about 1650 to 1760, both the Dutch and the English—depending on the state of international affairs—fought to possess the island in order to obtain a naval base on the very doorstep of France. And, at a more human level, Belle-Ile provided a home for a group of colonists exiled in 1755 from their lands in the New World. These exiles came from Acadia—now mainly the Canadian provinces of Nova Scotia and New Brunswick—where the imperial ambitions of France and England met. Although this settlement of refugees on Belle-Ile did not flourish as its sponsors hoped, it left an enduring heritage for the islanders and marks an extraordinary episode in the story of a resilient and independent people: the Acadians.

International treaties of the

seventeenth and eighteenth centuries gave the name "Acadie or Nova Scotia" to the disputed territory lying between New England and New France. Most of the Europeans who came to settle there were French, but there were also a number with English, Scottish, or Irish heritage. Between 1604 and 1713, the colony changed hands fourteen times, being claimed now by France, now by England, and once by the Netherlands. The people who lived in Acadia developed their own distinctive form of French, but English was known, and the colony had close enough trade relations with Massachusetts to consider Boston to be "our friend, the enemy."

During the eighteenth century, the Acadian lands were seen as increasingly important by both the English and the French. In 1713 the Treaty of Utrecht made the majority of the Acadians the French-speaking, Catholic subjects of the Protestant English crown. The next forty years of strife saw the Acadians attempt to pursue a policy of neutrality, but to no avail: the French believed the Acadians ought to have a fundamental loyalty to France, and the English suspected that they might. Although by the mid-eighteenth century the Acadians were an independent-minded group that scorned the schemes of empires, in 1755 the English decided to evacuate them as a security measure. The governor of the territory attempted to deport the entire population, sending more than 10,000 persons to other English colonies in the New World. Only a few thousand Acadians, including those who were still in French-controlled territory, escaped this deportation, an event the Acadians still call *le grand dérangement*.

For some of the Acadians, the deportation led back to the Old World, and by the conclusion of hostilities in 1763, some three to four thousand were established in the Atlantic ports of France as dependent refugees. These included approximately nine hundred persons who had had the misfortune of being dispatched to Virginia. The governor of that colony had refused to accept them, choosing instead to export them to England, where they had languished in detention camps as charges of the "Sick and Hurt Board" of the Admiralty. It was not until 1763, as part of the treaties ending the Seven Years' War, that these families, among others, were shipped to France to join the refugees already there.

Also under the treaties of 1763, the inhabitants and lands of Belle-Ile-en-Mer reverted to France, after having been in English hands for three years. The French quickly saw Belle-Ile as a place where some of the Acadian refugees might be resettled and returned to a productive, normal life. But the leaders of the Acadian exiles were bluntly unenthusiastic about this proposal. To a group that had suffered one deportation because their lands had become a battleground, the outstanding feature of Belle-Ile was its exposed position.

In a letter to the duc d'Aiguillon, one of the French officials concerned with their resettlement, the Acadians complained that "Belle-Ile is evidently more exposed to enemy attack than any other place in the realm, and in all probability we would find ourselves [there] in a similar situation to the one that has placed us today in such painful straits."

The vulnerability of Belle-Ile was by no means the sole reason for the Acadians' hesitation over the project. Very much North Americans, they saw little to sustain them on the wind-swept, nearly treeless island. As one French lawyer observed, the Acadians had lived in a country of abundance, with plentiful land and soil of infinitely better quality than that of Brittany. Although they knew how to fish, they were accustomed to consuming bread and milk and had contempt for a diet whose staples were fish and cider. They were accustomed to wood, not stone; forests, not quarries. The Acadians themselves wrote to the French officials to point out that given their almost total lack of experience with stone, they would need instruction and help from master stonemasons.

In addition, the Acadians feared that resettlement on Belle-Ile would do further damage to their already disrupted family ties. The deportation of 1755 had split apart a closely knit community of more than 10,000 people, and the majority of the exiles remained outside Europe, either in North America or the

Today, tourists are lured by the rustic charms of Belle-Ile, but the Acadians, deported from their homeland because of international conflicts, were reluctant to settle there. They felt that the island was vulnerable to attack, isolated from overseas communication, and deficient in resources.

Caribbean. The three or four hundred Acadian families that had reached France by 1763 were living in the seaports—the best places for gathering information about other refugees. In particular, the Acadians living in Saint-Malo and Morlaix enjoyed the charity of the duc de Nivernois, who was helpful in reuniting families separated over the previous eight years. Relinquishing such aid and leaving for regions not nearly so well placed for obtaining news from oceangoing vessels was a matter of considerable concern.

To understand how grave this issue was for the Acadians, it should be noted that in the New World, the Acadians had enjoyed a high birth rate and a low death rate, mainly due to their plentiful food supply and to the absence of most of the major epidemic diseases. As the North American colony grew, each village in it came to be joined to all the others by a web of marriages. By 1755 the descendants of a small number of original settlers were linked by extensive family relationships. The deportation, although it rarely separated husbands from wives or young children from their parents, broke apart these large extended families, separating older and younger generations and, above all, brothers and sisters. Records show that throughout their exile the Acadians searched relentlessly for their kin, gathering weeping on such occasions as the death of René Leblanc in Philadelphia, with only 16 of his 102 children and grandchildren

For centuries, the residents of Belle-Ile have made their living from both the land and the sea. The Acadians, accustomed to an abundance of bread and milk, were said to be contemptuous of the local diet, whose staples were fish and cider.

at his deathbed. The documents left by the heads of two families that finally settled on Belle-Ile showed a typical pattern: Michel Boudrot had a brother and sister-in-law in New York and another brother in New Orleans; Claude Dion was separated from ten brothers and sisters, who were distributed in Halifax, Boston, Plymouth, and New York, with only one in France, near Saint-Malo.

Like the Acadians, the natives of Belle-Ile's four parishes were ambivalent about the proposed resettlement. During this period the official directly responsible for the administration of Belle-Ile was Baron de Warren, a Scotsman who had been exiled after leading the last fruitless charge against Carlisle for Bonnie Prince Charlie. Although de Warren was filled with "eagerness and longing" to see the Acadians settled on the island, he quickly learned of opposition to the plan among the inhabitants of the parishes on the island—an attitude that had been fostered by the largest and most important parish, Le Palais. Local officials informed the baron in a letter of March 30, 1763, that the smaller parishes, "seduced by the bad example of Le Palais, have haughtily declared to Messieurs the officials that they do not wish to give up their villages to strangers." De Warren was further hampered by a continual and acerbic argument between officials at every level of authority—local, provincial, departmental, and royal—as to which budget should assume the costs of carrying out the projected settlement.

That some of the Acadians were finally settled on Belle-Ile was due in great measure to the persistence of the abbé Le Loutre, a missionary priest who had worked among the American Indians. Le Loutre, concerned with saving Acadian souls from the Protestant English, had actually helped to provoke the deportation whose ill-effects he now sought to alleviate. Once back in France, however, his concern turned to preserving the Acadian heritage from corruption by what he regarded as decadent French Catholicism. It was above all owing to the energies of this man, whom de Warren called the "grand mufti" of the Acadians, first, that in April of 1764 Louis XV paid the monies (56,000 livres) that the

crown had promised the Acadians as aid, and second, that the Acadians who went to Belle-Ile were granted exemption from all taxes for the first five years of the settlement. And it was through Le Loutre's efforts that in the fall of 1765 seventy-eight Acadian families were persuaded to set out to begin a new life on Belle-Ile. In a letter dated November 2, 1765, de Warren was able to write of the success of the venture, although, as he recounted, the last two boatloads of refugees, arriving from Morlaix, had to be rescued. The first boat had actually sunk, and the second had drifted dangerously close to the rocks at the harbor's edge. Fortunately, there had been no loss of life.

The Acadians were divided up among the four parishes of the island: twelve families went to Le Palais, north of the center of the island; thirty went to Bangor, to the south; twelve went to Locmaria, at the eastern end of the island; and twenty-four went to Sauzon, the parish at the western tip that later became Sarah Bernhardt's favorite summer retreat. As had been agreed, Louis XV paid each family for the building of a house; provided each with a horse, a cow, and various other livestock; and made available to the families of each parish a bull and a stallion. Further, so that the Acadians might begin life on Belle-Ile under the best possible circumstances, on their arrival each Acadian family was given three months' rations. One hundred ten pounds of tobacco was also delivered monthly for the Acadians' use.

The refugees were placed on Belle-Ile according to the personal plan of de Warren, who in correspondence with the abbé Le Loutre argued the question of how the Acadians should be organized. The abbé felt that, above all, the Acadians should be allowed to live as they had always lived, not mixed up with the *bellilois*, but as neighbors in a homogeneous community. The governor, however, replied that he found it "to the benefit of the service of the King and the interest of the provinces to distribute [the Acadians] equally in the four parishes on the island," pointing out that the refugees would "profit from both the advantages and disadvantages that each parish has." De Warren believed that only in this way would it be possible to establish "that unity and good harmony that must exist between the new settlers and the old, so that all come together with one spirit and make one people."

In 1765 Belle-Ile's native population was made up of some 375 families who worked the land and another 108 whose lives were more closely linked to the sea. De Warren reasoned that the Acadians would be more easily accepted and would be able to learn the local customs and pick up Breton—the common language on the island—if they were not permitted to retreat to the isolation of separate villages. His plan for the assimilation of the refugees was sensible enough, but before it could be tested any hope of establishing Belle-Ile as a center for Acadians in France was destroyed.

The crippling blows that were dealt the experiment came from both nature and French officials. To begin with, there was the climate. No sooner had the Acadians arrived on Belle-Ile than the island was faced with a drought that was to last six years, a drought of such severity that each year's crops barely yielded enough food for the current year, let alone seed for the next. Moreover, about the same time, the island's animals were struck with foot-and-mouth disease. The very basis of the new life was destroyed. Then came a major piece of bureaucratic bungling. In 1768 the office of the French comptroller-general demanded

payment from the Acadians of taxes that, according to the 1765 agreements, were not to have been due for more than a year. By the end of July 1768, Le Loutre was writing in despair to de Warren, predicting the failure of the scheme and already mourning the loss to France of "such good farmers."

There was, in fact, a deep conflict between the social expectations of the Acadians and the ideas of the *ancien régime*, the policies then forming a structured and rigidly codified French society. Perhaps more than anything else, it was this difficulty that led, almost inexorably, first, to the withering of a distinctive Acadian settlement on Belle-Ile and finally, in 1785, to the departure from France of almost all of the Acadians who had settled there. The story of the conflict can be read in much detail in legal records, and it is told, in part, with the vocabulary of *la capitation, la vingtième, les gargennes de fouage, la dixième*—all taxes with which the Acadians were eventually confronted. Although such taxes were a familiar burden to French peasants, they did not sit well with the Acadians, who even before they became untaxed refugees had paid no tax more onerous than the nominal penny-a-year quitrent required by the English. As colonists in North America, the Acadians had been immune to the threat of higher taxes, aware as they were of land reasonably close by but beyond the administrative reach of the official seats of government.

The majority of the 400 Acadians who settled on Belle-Ile in 1765 left within a few years, discouraged by natural calamities and by the burdens of French rule. Those who remained, however, were absorbed into the island's population, becoming bellilois.

The Acadians who settled on Belle-Ile were at least able to negotiate a temporary exemption from the French taxes, but they suffered a variety of other unfamiliar constraints. There were restrictions on hunting, on fishing, on moving about without passports. French court records of the time report the prosecution of Acadians found in ports and cities other than those to which they had been assigned and without the documents of identification that the French officials wished them to carry. Even the stiff official prose of the records cannot disguise the challenge that these second-, third-, and in some cases, fourth-generation North Americans made to the conventions of the France of Louis XV and Madame de Pompadour.

By 1772 three-quarters of the more than four hundred Acadians who had come to settle on Belle-Ile had left the island. Homeless once again, they tended to follow one of three routes. Some continued to wander, searching for a secure home in the Falklands, Santo Domingo, or Corsica, but all of their efforts failed to establish a central community for the refugees. A number of the Acadian families from Belle-Ile settled in other parts of France, slowly becoming absorbed in the life of the villages where their fortunes had led them: their descendants would be French, having perhaps a more romantic past than most of their neighbors. But the route by far most traveled by the newly displaced Acadians led back to the New World.

The Acadian heritage of Belle-Ile links the island's people to surviving Acadian communities in Canada and to the related Cajun population of Louisiana. In recent years, friendships have been established across the Atlantic as Acadians have traced their genealogical ties.

In 1783 a group of Acadian refugees living in the ports of Brittany sent a petition to Louis XVI, which read in part: "After twenty-eight years, after the loss of our property, we find ourselves in poverty and misery. The landlords daily refuse to house us, and without His Majesty's pay we cannot live. We are grieved that we are a burden." At this point, circumstances brought forward a sympathetic Frenchman, Peyroux de la Coudrenière. Peyroux had spent seven years in Louisiana, which was still a Spanish colony, and he had met the few Acadians who had settled there after passing through the British possessions in North America. He suggested that the Acadians remaining in France could also prove useful in Louisiana, a place where they might be much happier.

With considerable effort, Peyroux convinced the Acadians, the French officials, and the representatives of the Spanish government to adopt his plan. In need of settlers, the Spanish government agreed not only to pay the Acadians' transportation costs but also to subsidize them during the early years of their resettlement. Finally, in 1785, seven "Acadian expeditions" set sail from Nantes for New Orleans to join those Acadian refugees who had already settled in the parishes of Saint-Landry des Openousas, Saint-Gabriel d'Iberville, Saint-Louis de la Nouvelle-Orléans, and Saint-Martin des Atakapas. About 2,000 Acadians landed in Louisiana, and it is largely from this group that the distinctive Cajun population found there today developed. Although other immigrants also helped to form this people, the name "Cajun" emphasizes this Acadian origin.

The minority of Acadian families that remained on Belle-Ile after 1772, despite the initial setbacks, succeeded in adapting to the new life, eventually becoming *bellilois*. A census of the Acadians of Belle-Ile taken during the French Revolution identified 285 Acadians, 197 of whom had been born on the island. René Daligaut, the local antiquarian who in 1964 established a newsletter about the history of Belle-Ile, is convinced that there is no island family today that cannot claim an Acadian ancestor.

Today the Acadian communities of the Maritime Provinces of Canada, as well as the Cajun population of Louisiana, show an ever growing interest in the history of Belle-Ile-en-Mer. During the last thirty years delegations have crossed the Atlantic in both directions as Acadians have sought to trace genealogies and to establish friendly relations. The legacy of the Acadian refugees remains sufficiently vibrant for Belle-Ile-en-Mer to have held a festival celebrating the bicentennial of their arrival. Their sojourn is commemorated by a bronze plaque affixed to the archway of the town gate of Le Palais. And in the cemetery of Sauzon, weathered, lopsided headstones bring the names of Nova Scotia and New Brunswick to the eye. □

Olympic Mountain Goats

Introduced into the Olympic Mountains, these nimble animals have done so well that they are endangering plants that a national park is supposed to protect

by Michael Hutchins and Victoria Stevens

At home among wind-worn rocks and alpine meadows lying at or above timberline, mountain goats have adapted to an environment that is inhospitable by human standards. In the mountains, they have gained at least a temporary reprieve from the destructive byproducts of civilization—the pollution, urban expansion, and environmental deterioration that have pushed many lowland species to the brink of extinction. High above the clouds they can seem distant and removed—white shadows in a mountain mist.

The mountain goat (*Oreamnos americanus*) is not a true goat, but a goat-antelope. The only living member of its genus, its closest relatives are the mountain-dwelling antelopes of the Old World, including the chamois of Europe and the goral, takin, and serow of Asia. The species' natural range extends from Alaska to Idaho, Montana, and Washington in the United States, and includes Alberta, British Columbia, and the Northwest and Yukon Territories in Canada.

One of the best areas for observing these remarkable herbivores is in Olympic National Park, located on the Olympic Peninsula in northwestern Washington state. In the rugged Olympic Mountains they seem to epitomize the beauty of nature, and they are extremely popular with visitors to the 1,400-square-mile wilderness preserve. Appearances, however, can be deceiving. At present, the animals are the cause of considerable concern to park managers and conservationists. The problem is that mountain goats are not native to the Olympic Peninsula. Introduced to the region purposely, they may be causing significant changes in the natural ecosystem.

Mountain goats were introduced to the Olympic Mountains between 1925 and 1929, through the combined efforts of Washington state wildlife agents, the U.S. Forest Service, and a local sportsman's club. Records of the number of animals involved in the transplants are sketchy, but apparently eleven or twelve were released near Lake Crescent in the north-central portion of the peninsula. The animals came from Alaska and the Canadian Rocky Mountains near Banff, Alberta.

Why mountain goats were brought to the Olympic Mountains is not a matter of record, but since they have long been prized as trophy animals, the potential for establishing a harvestable population probably provided some incentive. At the time, the region was administered by the Forest Service, which has traditionally allowed recreational hunting on its lands. Long before the animals became numerous enough to hunt, however, much of the peninsula fell under the jurisdiction of the National Park Service. In 1933 control was transferred to the Department of the Interior, and in 1938 the area became Olympic National Park. Protected by federal law, the introduced goats proliferated, and current estimates suggest that as many as 700 may inhabit the region today.

The absence of native goat populations in the Olympic Mountains poses an interesting biogeographical question, particularly since the habitat is ideally suited to these animals and since they are native to the Cascade Range less than 100 miles to the east. A knowledge of the region's geologic history is essential to an understanding of the evolution and distribution of its flora and fauna and, ultimately, of the problems associated with the introduced mountain goats.

Isolated from other mountain ranges, the Olympic high country is surrounded by the waters of the Pacific Ocean, the Strait of Juan de Fuca, and Puget Sound, and by the lowlands of the Chehalis River Valley. Geologic evidence suggests that between twelve and twenty million years ago a shifting of the earth's crust created a mountain range running east to west across what is now the state of Washington. During this transformation, the regions to the north and south of the present Olympic Range were depressed, forming the Strait of Juan de Fuca and the Chehalis River Valley. A second event that occurred about five million years ago completed the isolation. At this time, the Olympics were elevated further, the Cascades were formed, and a concurrent down-folding of the area lying between the two ranges formed the Puget Sound Trough. During this critical period the subtle divergence of the Olympic ecosystem began.

Little is known about the evolution of mountain goats or the history of their dispersal, but it would appear that the events that isolated the Olympic Mountains had already taken place when the animals colonized the North American continent. Paleontologists have suggested that ancestral goats evolved in Asia and entered North America over the Bering land bridge that existed at various times in the geologic past. The skeletal remains of Pleistocene mountain goats, including those of a smaller, extinct species (*Oreamnos haringtoni*), have been found in eight separate localities ranging from the Yukon Territory to Mexico. The oldest-known remains come from British Columbia and date from the Sangamon Interglacial period, some 140,000 years ago.

Because of their isolation, the Olympic Mountains were not easily accessible to mountain goats or other Old World colonizers. The long-term isolation of the region is reflected in the presence and often abundance in the Cascades of at least seven other mammals that are not found in the Olympics. These include the pika, a small relative of the rabbits and hares; the Cascades red fox; and the Cascades golden-mantled ground squirrel.

Geographical isolation has also resulted in the evolution of animals that are endemic, or unique, to the Olympic Mountains. Not surprisingly, these are alpine species, since the alpine areas of the peninsula are effectively islands in a lowland sea. Prominent among these endemics is the Olympic marmot, a large colonially living rodent. Perhaps less noticeable, but no less unique, are twelve species and varieties of endemic alpine plants. Species unique to the Olympic Mountains include Cotton's milkvetch, Piper's bellflower, Flett violet, Flett fleabane, Webster's senecio, and rock spirea. The remainder are geographically distinct varieties of species that are also found in the Cascades, such as the mountain wallflower (*Erysimum arenicola* var. *arenicola*) and the Olympic rockcress (*Arabis furcata* var. *olympica*).

There is growing concern about the future of the delicately flowered alpine plants, particularly since their range overlaps that of the introduced

mountain goat. Apprehension about the potential effect of mountain goats on endemic plants and other organisms in the ecological community stems from the knowledge that alpine environments are among the most fragile of ecosystems, characterized by short growing seasons, low plant productivity, shallow soils, and harsh environmental conditions. These conditions, which include high winds, low soil moisture, and frequent freezing and thawing, combine with slow rates of plant growth to make alpine ecosystems such as those found in the Olympics particularly sensitive to disturbance. The common belief is that the most significant impact of herbivores on plant communities results from their feeding on vegetation, but in an alpine environment, trampling and digging may be far more deleterious.

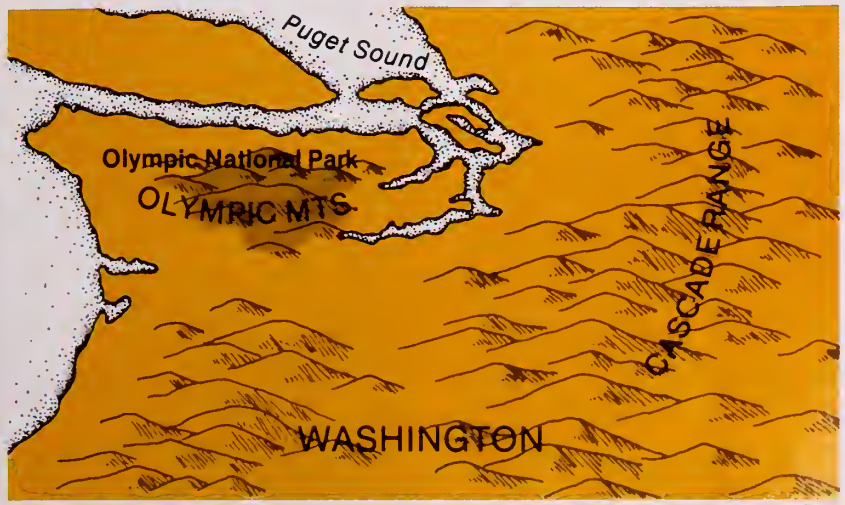
Since 1976 we have been studying the ecology and behavior of mountain goats in Olympic National Park with a twofold purpose: Besides seeking to increase our knowledge of the biology of this species, we hope to aid the National Park Service in developing a plan for managing the animals.

We conduct intensive field research from May through September, since inclement weather and the threat of avalanches make winter observations difficult. Much of our work has been done in a five-square-mile area in the northeastern portion of the park. Lying at an elevation of about 6,000 feet, this rugged terrain is the most densely populated on the peninsula, inhabited by as many as 165 mountain goats. Thus far, more than 100 of these have been marked with numbered ear tags for individual identification, and by following and observing known individuals, we have documented many aspects of mountain goat ecology and behavior in greater detail than was previously possible.

Superbly adapted for life in the mountains, the goats exhibit a distinct preference for rocky habitats, a trait

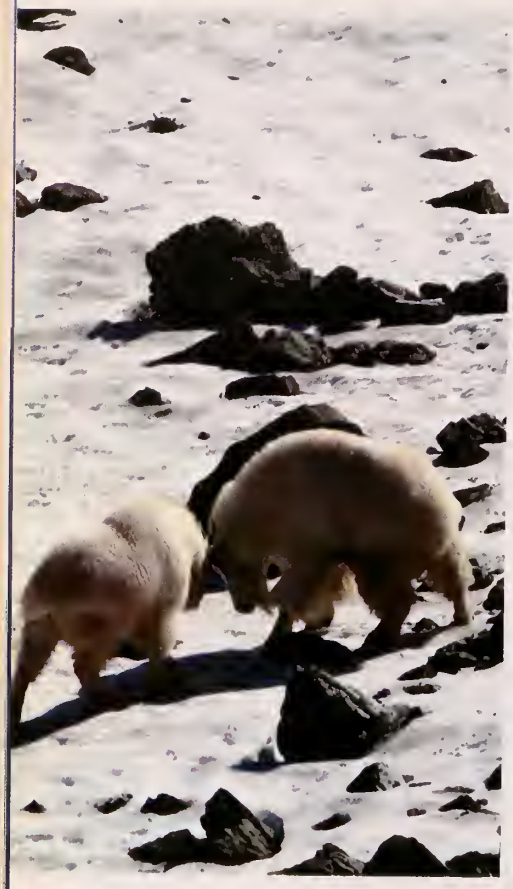
A mountain goat cools off by flinging soil over its body. The soil also provides some protection from insects. Erosion results wherever the goats create wallows for dust bathing.

Keith Gunner, Bruce Colemen, Inc.



that may have evolved as a means of escaping predators. Goats bed on or near rock outcroppings and kids are generally born in the protection of rocky cover. Although we have found little solid evidence of predation on goats in the Olympic Mountains, the region is frequented by cougars, bobcats, coyotes, and golden eagles; all have been known to prey on mountain goats in other settings. Only the cougar, however, is formidable enough to attack and kill an adult goat. Another major predator, the wolf, has been extinct on the Olympic Peninsula for nearly fifty years.

As is well known, mountain goats are accomplished climbers, their hoofs allowing them greater mobility on rugged, precipitous terrain than that attained by most other North American ungulates. Mountain goats are artiodactyls, or even-toed ungulates, having two toes on each foot. The outer edges of each toe are composed of a hard, bony shell that encircles a softer inner part. Unlike deer or elk, whose inner foot parts are concave, the mountain goat's inner foot is convex—an adaptation that provides for improved traction on smooth rock surfaces and more efficient use of small footholds in climbing. Vertical cliffs and rocky bluffs are an important aspect of the mountain goat's ecology not only because they provide a safe haven from predators but also because they offer freedom from deep snow and access to forage that is beyond the reach of other ungulates.



Another essential feature of the mountain goat's habitat is the alpine meadows, dense patches of grasses and herbaceous plants, which provide the animal's major food resource. Mountain goats are generalists and will utilize nearly all available plant species. Like most animals inhabiting temperate regions, mountain goats must cope with seasonal fluctuations in food availability. The plant communities on which they subsist are composed primarily of perennials, which maintain vegetative parts such as leaves, stems, and flowers above ground for only a short time each year. During the winter most alpine plants are dormant, saving their energy for more favorable weather in the spring. This dormancy coincides with a time when major portions of the vegetational habitat are covered with deep snow, making them inaccessible to hungry herbivores. In some regions, mountain goats may exhibit vertical migration, moving down to lower altitudes where there is less snow and food is more readily obtainable. During the summer, when food is abundant, the animals consume quantities in excess of their daily needs. Their indulgent eating habits result in an accumulation of fat, which helps to sustain them during the lean winter months. Since 1976, nine mountain goats have been found dead in the park. Most mortality is apparently the result—direct or indirect—of winter malnutrition. Several of the dead goats were killed by accidental falls, which are more likely if an animal is in a weakened condition.

Like most artiodactyls, mountain goats are ruminants: ungulates with a four-chambered stomach. The first and largest of these chambers, the rumen, contains colonies of bacteria and protozoans specialized for breaking down carbohydrates and cellulose—the major constituent of the cell walls of plants. Since ruminants lack some necessary enzymes, they rely on "hitchhiking" microorganisms to aid them in digestion. Through a complex fermentation process, these symbionts manufacture essential amino acids, synthesize water-soluble vitamins, and convert cellulose into volatile fatty acids. The latter are absorbed directly through the rumen and are an important source of energy. The microorganisms themselves are digested as they pass through the intestines and provide the ruminant with protein needed for bodily growth and maintenance. In addition, the rumen serves as a holding tank for unchewed food eaten quickly during limited foraging

Swiping horns, two males contest the spot on which the smaller one had been lying, above. The larger male, which was dominant, won the spot from his subordinate after a few harmless swipes. Males engage in such competitive behavior throughout the year, but with the approach of the breeding season the seriousness of the bouts escalates. The goats' sharp horns can inflict heavy damage to an opponent, and the loser of a bout can be killed. In general, dominant males do most of the breeding. Some subordinate males may not breed at all. On Mount Angeles, right, mountain goats forage through the winter snows. If the snow cover is heavy, the goats will move below the 6,000-foot elevation in search of food.

Keith Gunnar

periods. Such food can be regurgitated and chewed while the animal is at rest, as in the familiar cud chewing of domestic cows. The primary advantage of the rumen is that it allows an animal to subsist on relatively low-quality food by increasing the efficiency of the digestive system.

Mineral licks are another important aspect of the mountain goat's ecology. The animals have a craving for salt, which seems to peak in late spring and early summer. This peak coincides with the time in which they are making a transition from low-quality winter forage to newly emergent vegetation. Physiological studies have shown that an ungulate's ability to retain sodium—an element necessary for many bodily functions—is influenced by diet. Ingestion of newly emergent and highly succulent vegetation increases the loss of sodium in the feces, and the animals may compensate for this deficiency by consuming the substance directly. More recently, however, studies of the chemical composition of natural mineral licks suggest that sodium may be a relatively rare element, and that ungulates may actually be seeking inorganic sulfur in the form of sulfates. These substances are converted in the ruminant's digestive system into amino acids, such as cystine, which are essential for hair growth and lactation.

There are no natural mineral licks in the Olympic Mountains that are known to be used by goats, but the remains of a large artificial salt lick still exist. National Park Service officials stopped providing salt for goats several years ago when they noticed that excessive trampling in the area of the lick was resulting in habitat destruction. The area is now almost completely devoid of vegetation, but the animals still use the lick extensively, apparently seeking minerals that have percolated into the soil. (Hikers sometimes unwittingly increase such deterioration by pausing to relieve themselves by the trail. Human urine has a salty taste and is very attractive to mineral-starved goats. The trampling, digging, and licking by animals at these sites can be a factor contributing to erosion.)

Mountain goat summer range must also provide a variety of microhabitats that aid the animals in thermoregulation. During the course of a year, mountain goats are subjected to extremes of both hot and cold, and their body temperature is regulated through physiological and behavioral means. The goats' long, dense fur, which helps to reduce heat loss during the winter, is shed during the summer when temperatures may soar over 90°F. Ruminants are particularly susceptible to overheating since their digestive system has a built-in "furnace." The colonies of microorganisms, which break down cellulose, generate heat as a result of their own metabolic processes. This heat, combined with a goat's own heat and with solar radiation absorbed from the environment, can result in thermal stress if there is no compensating movement into a cooler microhabitat. On a hot day, the animals typically seek shade or recline on patches of snow. When overheated or harassed by insects, a goat may also lie in dirt and, with a quick movement of a foreleg, throw cool soil over its body. This behavior is a further cause of erosion, resulting in the creation of wallows, large patches of exposed soil used regularly for dust bathing. Once the soil surface has been disturbed in this manner, erosion is initiated and can be expected to continue even in the absence of goat use.

The white coat of the mountain goat may also function in thermoregulation. The white color might be a form of protective coloration and, in fact, predators may find the goats more difficult to see when the mountains are hidden by a veil of snow. Such an advantage does not extend into the summer, however, when snowfields melt and alpine meadows fill with lush green vegetation. The traditional view is that in this season the white coat may act to reflect solar radiation and so keep the goats cool; but recent physiological studies have also shown that in a windy environment, such as the mountains in winter, more heat is absorbed by a light coat than by a dark one.

Many areas of the Olympic Mountains possess the essential components of the mountain goat's habitat. The distribution of such favorable ecological characteristics has influenced the population growth of these introduced herbivores and their pattern of distribution. Parkwide surveys have confirmed that the animals now inhabit nearly all of the region's suitable habitat, and birth and dispersal rates suggest that the population is still expanding.

Since 1977, 20 percent of the animals tagged in the high-density study

Michael Hutchins

Flett violet, above, is one of the alpine plants threatened by the grazing and trampling of the goats. Convex inner foot parts enable the two kids to gambol on the face of a rock wall, right.

site have moved to other parts of the peninsula. Such movement has not been observed from areas of lower density. Most long-distance travelers have been young males, but some adult females with kids have left the crowded conditions and moved as far as fifty miles away. Adult females usually exhibit a strong affinity for a particular home range, never moving more than six miles in any direction. The dangers associated with leaving familiar territory are considerable. Dispersing animals move into environments where they have no knowledge of the location of food or other essential resources. On the other hand, young males are often excluded from breeding by older, more dominant individuals and therefore may benefit by seeking a less competitive social environment. Adult female goats do not compete for mates, but competition for resources might be expected to influence their behavior. As a result of the movement of adult females out of the high-density study area, some of the smaller outlying populations have grown significantly in the past two years. Without exception, females in these less crowded areas have a higher birth rate than those in the high-density site.

The social life of mountain goats is as fascinating as their ecology and demography, and the Olympic Mountains provide an ideal laboratory for detailed behavioral study. The marking of many animals for individual recognition has greatly facilitated our work. In the past, few long-term studies have been conducted on mountain goat behavior. Indeed, one authoritative book on mammals still incorrectly describes the species' mating system as monogamous. Actually they are polygynous: a dominant male may mate with several females and some subordinate males may not mate at all. During the rut, in late November and early December, the competition for access to estrous females may be intense. Males threaten each other by hunching their backs, presenting their broadsides, and swiping upward with their horns while circling around each other head to tail. They may also sit next to each other and paw the ground repeatedly with one foreleg. Their digging results in the formation of the so-called rutting pits.

Similarities in the appearance of the sexes has probably contributed to the monogamy myth. Although adult males may weigh up to 250 pounds and are on average 30 percent heavier than females, both sexes possess true horns, which continue to grow throughout an individual's lifetime. The horns are dagger sharp, and although they are often used only to threaten other goats, fights occasionally become more serious. Males may carry the scars of many battles and have been known to kill each other while fighting over a female.

During the summer months, adult females, juveniles of both sexes, and kids congregate in nursery bands. These are loose aggregations that include anywhere from two to more than fifty individuals. Adult males and females seldom interact with each other outside the rut, except when both sexes use the salt lick in late spring. During the summer, males may be solitary or travel in small groups of two or three. A similar pattern is seen in bighorn sheep, and some behaviorists have speculated that this spatial segregation may reduce competition between males and their offspring. The same may be true of mountain goats.

In mountain goat society, females, or "nannies," are highly competitive and intolerant of one another. Although gregarious, they have a well-defined personal space with a radius of about three to six feet. Any intrusion into this space by an individual other than offspring usually results in aggression or avoidance. Some of the patterns of aggression seen among females are similar to those exhibited by males and include broadside displays, as well as lowering and presenting the horns. Aggression among

Tom and Pat Leeson

females is observed most frequently at the salt lick, which is a concentrated, defendable resource.

Our behavioral studies have focused primarily on mother–offspring relationships. Females usually produce a single kid, but twins are also seen on occasion. Born in late May or early June, the kids are highly precocious, being able to stand and walk only a few hours after birth. Mountain goat kids can be classified as followers rather than hiders. More precisely, many ungulates, including deer and elk, deposit their young in a thick patch of vegetation and leave them alone. While their mothers are foraging, the deer fawns and elk calves lie motionless, thereby reducing the possibility of being seen by predators. In contrast, mountain goat kids only a few days old follow their mothers, rarely straying more than a few yards away. In the goats' open alpine habitat, hiding would be difficult.

Nannies are generally intolerant of strange kids and may chase or threaten them if they come too close. Recognition of young seems largely olfactory, and nannies commonly smell their young upon being reunited with them after a brief separation. Mothers and kids may also recognize each other's calls, since voice recognition has been described for other ungulate species, such as reindeer and domestic sheep. The common response of a kid separated from its mother is to run frantically from one female to the next, bleating loudly. Such calls are also given when kids fall several yards behind their mothers during routine foraging or travel. Females may respond to vocalizing kids by calling or by looking for their offspring.

Like other mammalian young, mountain goat kids are nutritionally dependent on mother's milk during the early stages of their development. For a time, mothers may initiate nursing by placing themselves in favorable positions, and permitting the young to nurse until satiated. Some nursing bouts may even be terminated by the offspring. This pattern changes over time, however, and mothers become progressively less willing to allow access to their teats. This weaning process prompts kids to seek nourishment elsewhere, and they begin to forage regularly on vegetation. Female mountain goats begin to reject their offspring's attempts to nurse within the first week of life, using a variety of methods. For example, a mother may step over the offspring and walk away or she may give a quick stamp of her rear leg. Unless their offspring are particularly persistent, females are seldom aggressive in this situation.

Little is known about the breakdown of mother–infant bonds in ungulates. Previous studies have suggested that mountain goat young remain with their mothers for about eleven months, and that this relationship is severed just prior to the birth of a new kid. Some investigators have suggested that severance of mother–infant ties is due primarily to maternal intolerance, whereas others believe that yearlings leave on their own initiative. Our observations suggest that nannies do become intolerant of their yearling just prior to the birth of a new kid, but females that become barren may extend the period of maternal affiliation for up to two years. We observed several cases in which females maintained consistent association with their yearlings or two-year-olds. Such relationships are similar to those seen between mothers and kids and involved relatively frequent, friendly contact.

Retaining offspring may convey a number of advantages. To begin with, reproduction requires energy, and factors such as the quality of available forage and the amount of competition for food resources can be expected to influence a female's ability to produce offspring in any given year. Barren females or those that lose their young to predators, accidents, or disease may be able to increase their older offspring's chances of survival and competitive ability by continuing to associate with them. For example, we have noticed that retained yearlings and two-year-olds share in the relatively higher dominance status of their mothers, particularly at defendable resources such as the salt lick. Young retained by dominant females often utilize the lick at the same time as their mothers, while their less fortunate peers wait on the periphery. Retained offspring also nurse occasionally, although we have not as yet been able to determine whether their mothers continue to produce milk. They nurse far less frequently than kids, and the practice may simply represent the kind of nonnutritive "comfort suckling" seen in many young mammals. The mothers may also gain some immediate advantages from the extended period of association. We

have observed yearlings grooming their mothers, and in one case, a retained offspring paid particular attention to its mother's badly wounded eye. Such aid-giving behavior may help reduce the risk of infection and increase the probability of survival.

Unattached yearlings or two-year-olds, although they are not tolerated in the same way as retained offspring, often attempt to follow adult females. This finding suggests that there may be some advantage to associating with an older individual. For example, young animals may learn the location of prime feeding areas by following adults that have a better knowledge of the home range.

The introduced mountain goats of Olympic National Park represent a difficult and complex problem for the park service. The alpine wilderness of the Olympic Mountains provides an excellent habitat for these animals, and these nonnative herbivores may be altering the composition of plant communities and even endangering some rare endemic varieties.

Botanical studies initiated by Ingrid Olmsted, and expanded by Douglas Pike and William Pfitsch of the University of Washington, suggest that the introduced mountain goats have reduced plant cover, increased erosion, and shifted plant-community dominants toward more resistant or less palatable species. Unfortunately, only a limited amount of information exists about the structure of this plant community prior to the introduction of the goats, but noticeable changes have been observed since these botanical studies began. In addition, mountain goats are known to graze on at least three of the endemic plants. Such grazing results in the removal of a significant number of flowers—the potential source of seed for future generations. If sexual reproduction from flowers is more important than asexual, or vegetative, reproduction in these plants, then overgrazing could ultimately result in a decrease in the size of their populations. The effects of grazing, combined with erosion caused by soil disturbance and with competition from disturbance-adapted plants, could eventually lead to the extinction of some species. Feral domestic goats are known to have eliminated many species of indigenous plants in the Galápagos Islands and other island ecosystems.

Detailed analyses of exclosures—fenced areas built to exclude mountain goats—suggest that the recovery of badly damaged meadows will proceed slowly if at all. Studies by Ed Schreiner of Olympic National Park indicate that similar meadows damaged by as few as 500 passes by human hikers may take up to 100 years to recover. The congressional act of 1916 that established the National Park Service specifies the preservation of natural ecosystems as one of the organization's primary responsibilities. According to a frequently quoted passage, the service's purpose in the lands it controls is to "conserve the scenery and natural and historic objects and wildlife therein and to provide for the enjoyment of the same in such a manner and by such means as will leave them unimpaired for the enjoyment of future generations." To fulfill this obligation, the Olympic mountain goats and, for that matter, all introduced species should be removed or at least carefully controlled on lands under park service jurisdiction. However, practical and political obstacles to such a management plan abound. The political implications are particularly significant, since the National Park Service is a federal agency whose actions are subject to public scrutiny. Ironically, the animals have long been promoted as a tourist attraction and have even been featured on posters advertising Olympic National Park.

The concern over public response to a management plan that would remove introduced animals from federal lands is based on previous experience. Attempts to control feral burros in Grand Canyon National Park have met with serious opposition. Released by prospectors about the turn of the century, the burros successfully adapted to the environment and reproduced prolifically. Indeed, as early as 1924, park managers noticed that the burros' foraging and trampling were having an impact on the canyon's fragile ecosystem. Periodic efforts at controlling the animals, made between 1924 and 1969, resulted in the capture or shooting of nearly 3,000 burros, but complete eradication was never achieved. These attempts at controlling the animals came to a halt when groups began protesting the killings. The dispute eventually led to a court battle, and the issue is still not resolved.

Some wildlife managers have attributed emotional outbursts over the killing of feral burros to a sociological phenomenon termed the Bambi syndrome, after the animated Disney character. Public attitudes about animals and nature have certainly been influenced by anthropomorphic characterizations in books, films, and television. Regardless of the factors responsible for such attitudes, however, there are those who believe that burros have a right to life and that they should be kept in the park for people to enjoy. Still others contend that the animals' continued presence may result in the destruction of a natural ecosystem that took many millenniums to evolve. Once destroyed, such systems cannot be replaced.

Understandably, park service officials must exercise care in their preparation of a mountain goat management plan for Olympic National Park. Research efforts are continuing, and management options will be presented for public review. Not all management options call for destroying the entire population. For instance, it might be possible to restrict the animals to particular areas of the park and carefully control their numbers. Alternatively, it may be possible to capture and transplant at least some of the animals to locations in their natural range. Humane treatment of the animals is an important consideration, and a detailed knowledge of mountain goat ecology and behavior will be essential to the development of management alternatives.

The controversy surrounding the management of introduced species has focused increased attention on some difficult philosophical questions. What is the function of our national park system? And should the park service's primary responsibility be to preserve natural ecosystems in as pristine a state as possible or simply to provide the public with enjoyable places for recreation? As human population growth, urban expansion, and an ever increasing demand for resources reduce our once-abundant natural areas to mere islands of wilderness, questions of this kind will assume considerable importance. □

During the mating season, corneal glands at the base of a male's horns secrete a liquid that stains the lower part of the horns. The secretion may be rubbed on bushes as a means of expressing dominance.

A Voyage in the East China Sea

The first Sino-American oceanographic project in more than thirty years investigates sediment discharge in shallow coastal waters

by John D. Milliman

China, with its rich cultural and political history, has long attracted the interest of the Western world. For a marine geologist, this vast country holds a special fascination since oceanographic features unique to China may be the key to understanding both modern and ancient geologic processes. Now, the expansion of relations between the United States and China is enabling scientists from the two countries to join in exploring China's remarkable waters.

Perhaps the most important feature of this kind is the presence of two huge rivers that drain much of the Chinese countryside—the Chang Jiang (Yangtze), the longest river in China, and the Hwangho (Yellow), the second longest. In terms of sediment discharged into the ocean, these rivers annually contribute a combined total of nearly two billion tons, or about 15 percent of the total world budget. The volume of sediment derived from the rivers each year equals about one-half of a cubic mile, or about four times the total volume of material used to construct the Great Wall of China. Of the two rivers, the shorter Hwangho, although it has a far smaller water discharge, has by far the larger sediment load, the result of its draining the loess plateaus of northern China of silt-sized sediments deposited during Pleistocene glaciations. The fine-grained, easily eroded sediment accounts for most of the 1.4 billion tons of material carried downriver each year to the sea by the Hwangho and is what gives the "Yellow River" its name.

The Chang Jiang, while carrying a smaller sediment load (about 550 million tons, nearly twice that of the Mississippi), is the fourth largest river in the world and not only provides China with water for agriculture but also serves as a major transportation route to the interior of the country. Nearly half of China's one billion people live in the watershed of the Chang Jiang, and Shanghai, at the river's mouth, is the country's major port and

The American research vessel Oceanographer *riding at anchor off Amoy, a coastal city about 500 miles south of Shanghai.*

Frederick J. Hoetzl

Joe Le Monnier

largest city, with a population in excess of eleven million.

Another feature of China's marine geology that is of particular interest is the very broad continental shelf in the East China Sea. Shelf widths are greater than 300 miles (more than twice the width of most other shelves), giving this shelf dimensions approaching those of the epicontinental seas, those ancient, broad, shallow seas that spread on the continents and from which thick sequences of sediments were deposited. Many of the substantial Paleozoic and Mesozoic sedimentary sequences in the central United States, for example, accumulated in waters substantially shallower than 300 feet. The East China Sea is one of the few modern analogs of an epicontinental sea. Hence, by learning how sediment enters and accumulates in the East China Sea, we may begin to understand how the ancient epicontinental seas developed. Moreover, the shelf of the East China Sea is the site of an extremely active fishing industry and may also hold vast stores of petroleum, two factors that make its study economically as well as scientifically interesting.

Because of China's recent turbulent history, neither the country's large rivers nor the East China Sea have been studied in detail by modern oceanographic methods. Political considerations kept Western nations from working off the China coast for the last thirty years, and kept many Soviet-bloc countries from working there for the last twenty. More importantly, the Cultural Revolution played havoc with Chinese research efforts. Many leading Chinese marine scientists spent part of the decade from 1966 to 1976 working on farms and in factories rather than in scientific institutions. Entire laboratories were closed, and the flow of foreign journals into most scientific libraries was cut off completely. Some Chinese libraries I have visited have gaps as great as six years in their collections of Western journals. Hence, at a time when the marine and earth sciences were flourishing outside of China, with a proliferation of data on such subjects as plate tectonics and continental drift, inside the country these disciplines languished. At the end of the Cultural Revolution, when contacts with Western countries were finally renewed, Chinese scientists found themselves in much the same situation as Rip van Winkle: while time had stood still for them, the rest of the world had changed markedly.

In the past four years scientific exchanges between China and other countries have increased dramatically. Chinese scientists now regularly attend international conferences and visit selected scientific institutions in the West. Through these ever increasing contacts, Chinese scientists have been brought abruptly into the 1980s. In the marine sciences, ships and new equipment are being built and purchased at a pace that would make any American oceanographer envious. (Not entirely facetiously, I asked several of my Chinese friends if we could import the "Gang of Four" to the United States in order to hasten the acquisition of newer and better equipment and ships.)

It was under these circumstances that a group of eleven U.S. marine scientists set out this past summer to work with a group of fifty Chinese scientists in the East China Sea and the Chang Jiang River. The group from the United States was interested in studying processes related to the Chang Jiang River and the broad continental shelf. Our Chinese colleagues were interested in learning more about U.S. technology and approaches to scientific problems.

The program stemmed directly from a cooperative research agreement on sediment dynamics, signed in the spring of 1979 between the National Bureau of Oceanography of China and the National Oceanic and Atmospheric Administration (NOAA) of the U.S. Department of Commerce. Unlike many government-to-government agreements in which the work is handled almost exclusively within governmental agencies, both sides agreed that much of the work would be done by scientists from universities and independent agencies. The Chinese scientists came from various universities, research laboratories, and governmental bureaus. In the American delegation, a total of eight universities and research institutes from different parts of the country (in addition to NOAA personnel) were represented. (Additional funding for the project was supplied by the U.S. Office of Naval Research and the National Science Foundation, and the National Geographic Society provided some travel money.)

To understand the interaction between the Chang Jiang River and the East China Sea a number of specific but interrelated questions must be answered: (1) How are the water and sediment loads (both suspended and dissolved) transferred from the river to the sea? (2) Where is the sediment transported after introduction to the sea at present and where was it transported within the recent past? (3) How are the transfer and transport of sediment affected by the current and tidal regimes of the area? (4) What is the interaction between the sediment and benthic organisms (those found on the sea floor)? On this last point, it is important to understand that in areas with relatively low rates of sediment accumulation, organisms can significantly alter depositional patterns through biological activities, enhanc-

ing or retarding the processes of deposition and/or erosion and altering the chemical composition of both constituent grains and pore waters. In the inner East China Sea—where the rates of sedimentation appear to be high—one might suspect that the role of organisms would be somewhat reduced, with the rapidly accumulating sediment restricting the activity of many species and, in general, masking organisms' biological impact on the sediments.

Finally, to understand completely the interaction of the river and the sea, we must consider the recent history of the area. Two points are of particular interest. First, during the last glaciation, about 30,000 to 18,000 years ago, sea level fell as much as 300 to 400 feet below the present-day level—a result of the utilization of seawater in the buildup of continental glaciers. Although there is little sea-floor evidence to show the former path of the Chang Jiang, we believe that during the maximum lowering of the sea level the river's path extended across the emergent continental shelf and emptied into the Okinawa Trough. As the sea transgressed over the continental shelf during the last glacial melting, 5,000 to 15,000 years ago, the Chang Jiang River channel was probably buried by sediment, so that no present-day trace of it can be seen on the sea floor. The location of this relict channel, and its dimensions, are therefore not known.

The second point of interest is the effect of human activities on the sediment load carried by Chinese rivers. This impact is difficult to gauge. Poor agricultural practices over the past several thousand years have greatly increased erosion of the land. As a result, the high sediment loads that characterize China's rivers may be far greater than the prehistoric loads.

To grasp fully the interrelations between these various processes and problems requires the integration of a number of separate but interacting disciplines, among them, geology, physical oceanography, chemistry, and biology. The American group included scientists prepared to study the transfer of Chang Jiang water to the sea, the movement of Chang Jiang water and other water masses in the East China Sea, the transfer of dissolved and suspended loads to the sea, the movement of sediment on the surface of the sea floor in response to currents and waves, the geotechnical properties of sediments and their history, the morphology and shallow structure of the sea floor, the rates of deposition of sediments and their chemical alteration, and the effects of biological interaction on bottom sediments.

To carry out a program that addressed such a diversity of topics, several ships and many well-coordinated schedules were required. After considerable negotiation, a decision was reached to undertake a preliminary cruise in June of 1980, so that the scientists from the United States could learn more about the river and its adjacent shelf and scientists from each country could evaluate the equipment and techniques of the other. Three ships were to be used, one from the United States and two from China, and scientists, equipment, and crews from the two countries were to be exchanged. One of the Chinese ships (*Shu Guong*, or *Dawn #6*) would work in the Chang Jiang estuary, studying the transfer of water and sediment loads to the sea; the other Chinese ship (*Xiang Yang Hong*, or *Turning Red by the Sun #9*) would be responsible for sampling sediment throughout the entire area and for making oceanographic observations on the in-

Transfer of sediment from the Yangtze River to the East China Sea can be seen in this composite picture made from two Landsat satellite images of the mouth of the river. Although both images were made at an altitude of 570 miles, the one at the right dates from April 1975 and the one on the left from August of 1979. Runoff is greatest during the rainy season, from about June through August, but as is shown here, heavy cloud cover in this period interferes with satellite imagery.

NASA Landsat photographs

nermost shelf. The American ship, R/V *Oceanographer* (from NOAA, Seattle), was to be responsible for deploying several arrays of current meters on the shelf, for taking hydrographic measurements of waters on the middle and outer shelf (at times coordinated with the observations made by the Chinese ships), and for carrying out most of the geophysical and geomorphic studies.

This was to be the first cooperative oceanographic field program between scientists of two countries that had been antagonists for the preceding thirty years, and as might be expected, many areas of potential conflict had to be straightened out prior to the departure of the ships from Shanghai. Some points of contention (such as who would ultimately retain the original data) were not agreed on until a few hours before the ships sailed. Moreover, the exchange of equipment and personnel between ships presented countless problems. For instance, consider the difficulties of trying to operate U.S. instruments on Chinese ships wired for different electrical power and equipped with different ocean winches. Nevertheless, our agreement on the ultimate objectives of the project made us optimistic about the forthcoming cruise.

The three ships sailed from Shanghai on June 9, 1980, marking the beginning of what was the first international cooperative study of the Chang Jiang River and its adjacent waters. Sailing out the Chang Jiang from Shanghai is an intriguing experience for scientists and nonscientists alike. As we approached the mouth of the river, the tan waters turned brown near the ever present shoals. Where ship propellers stirred the bottom, the water became dark brown, creating a patchwork of tan, brown, and chocolate. Across this mosaic sailed a wide variety of craft—modern cargo ships, junks, fishing boats, and even the occasional passenger liner—most of them go short distances to and from Shanghai, but some go as far upriver as Chungking, more than a thousand miles from the coast.

During high river runoff in the summer, the tan-colored freshwater plume can extend many miles offshore. About thirty-five miles from the coast, however, the bottom deepens, the water becomes more saline, and the suspended sediment settles from the surface. The increased clarity of the water stimulates the growth of plankton in the nutrient-rich, river-derived water, turning the offshore water green. This proliferation of plankton ultimately results in a high production of fishes, which, in turn, attract hordes of fishing boats of all sizes, most of them from China, Japan, Taiwan, and Korea. (When towing scientific instruments from an oceanographic ship, one must always keep a lookout for small fishing boats that might dart across the wake and cut the towing cables.)

The *Shu Guong #6* carried eighteen Chinese scientists and technicians and five American, and its work was restricted to the river and estuarine waters. Among other tasks, this ship was assigned to anchor at a series of specified stations for 27-hour periods, so that variations in temperature, salinity, currents, and dissolved and suspended loads could be monitored. As the tide rises and falls, the discharge of river water decelerates and accelerates correspondingly. Maximum currents are associated with ebb tide and minimum currents with flood tide. During the maximum outflow, we found suspended sediment present in amounts that periodically exceeded four grams per liter—concentrations 100 to 5,000 times higher than those recorded in offshore waters. Perhaps even more interesting was the observation that most of the water and sediment from the river hugs the southern coast as it leaves the river mouth, apparently little of it escaping directly offshore or to the north.

The team on the *Xiang Yang Hong #9* included thirty-five Chinese and seven Americans. Despite the considerable problems the Americans encountered in working with Chinese equipment, this group was able to obtain numerous geologic and biological samples from the bottom. In nearshore areas, the fine-grained bottom sediment was highly laminated, suggestive of rapid accumulation. Interestingly, farther offshore the sediment was coarser, but also laminated. D. C. Rhoads of Yale University feels that these sands are periodically resuspended by currents. This would prevent colonization by benthic organisms, thereby giving the sediment its laminated character.

The team on the *Oceanographer* also included more Chinese (thirteen) than Americans (five) and its work was concentrated in mid-shelf areas. Profiles of the water column, using conductivity, temperature, and depth probes, showed the offshore waters to be a two-layered system, with warmer, less saline waters overlying colder, more saline waters. The density gradient between the two is remarkably sharp. Suspended particles above the gradient are composed primarily of biologically produced material, while the bottom waters mostly contain sediment from the river, suggesting that the two layers are almost decoupled from one another. Occasionally, plankton concentrate at the density discontinuity—a phenomenon that has often been observed elsewhere.

Mapping the sea floor revealed that much of the bottom of the East China Sea consists of well-rippled sand, although some areas were unrippled or included only scattered outcrops. Subsurface seismic profiles crossed a number of areas in which filled channels—possibly those of the Chang Jiang—could be detected. The depth of the channel indicates that it was probably riverine until about ten thousand years ago, after which it became filled with about eighty-five feet of sediment. Further profiling in the area should delineate the extent of this buried channel.

Only a few months have passed since the U.S. scientists returned home and an even shorter time has elapsed since all of our samples arrived. Clearly, it is too early to draw any far-reaching conclusions about the significance of our observations from this one cruise and there is no question that further cruises are needed. One is already planned for the summer of 1981, during flood season, and one for the late autumn of 1981, when runoff should be far lower. Observations made during the initial 1980 cruise will help define areas of special interest that should be studied further. It is already apparent that the region of the East China Sea immediately south of the Chang Jiang, where most of the river water appears to escape, warrants such attention. Now that Chinese and U.S. scientists have worked successfully together once, future efforts should go more smoothly. It is perhaps fitting to note than even with the problems of logistics and equipment and a variety of bureaucratic snags, all the U.S. scientists are eager to continue the studies next year. Considering that for most of us our first introduction to China and its oceanography took place less than a year ago, we have moved very far very quickly. □

DINOSAURS BY MAIL

Distinctive umbrellas and totes, and other rare species from The Museum.

Dinosaur Umbrella, 48″ diam. Cotton poplin. Burgundy/beige. Wood handle. #120 **$25.** Members **$22.50.**

Food and the Fetus

Pregnant women are now being advised to gain more weight than was previously recommended in order to insure survival of the fetus and the newborn infant

by Myron Winick

Over the past few years, one of medicine's fundamental beliefs about pregnancy and the development of the human fetus has been challenged. Until recently the fetus was viewed as a parasite capable of extracting the nutrients it needed from the vast stores contained within the mother's body. For this reason nutrition during pregnancy was not considered very important for the average mother, and weight gain was kept to a minimum with the rationale that this would protect the mother from future obesity and in no way affect the growth and development of the fetus. We know today that neither of these statements is true. Weight restriction during pregnancy will not protect the mother from future obesity and the fetus will not grow properly if the mother's weight gain is insufficient. To understand why this is true, it is necessary to examine some of the physiological adjustments that a woman's body makes during pregnancy and the way in which these adjustments are affected by nutrition.

Early in pregnancy the uterus begins to grow in order to accommodate the developing fetus. In addition, the blood flow to the uterus increases markedly since much more blood will be necessary to supply the nutrients and remove the waste products passing to and from the fetus through the placenta. For this increase in available blood to take place without interfering with the mother's own needs, her total blood volume must also increase. Thus early pregnancy is characterized by a series of changes that include an increase in maternal blood volume, an increase in uterine blood flow, and the development of the placenta with its rich blood supply. Recent studies have shown that inadequate nutrition affects all these processes, reducing the increase in maternal blood volume and both uterine and placental blood flow. If the mother is undernourished early in pregnancy, the "lifeline" to the fetus will be inadequate and nutrients will not be efficiently transported to the fetus.

As pregnancy proceeds, the mother undergoes further adaptation to insure proper fetal nutrition after birth. The breasts, which will become the organ capable of producing the infant's total food supply, begin to grow and to develop the capacity to synthesize milk. In addition, fat is carefully laid down in deep sites within the body to store the energy necessary for lactation. The mother will expend more energy during the period of lactation than at any other time of her life, and her body begins to prepare for this effort during pregnancy. In fact, the preparations for lactation are so important that if the mother is inadequately nourished, they will take place even at the expense of fetal growth. The logic of this system is more easily understood when we remember that until the advent of infant formulas before the turn of the century, no infant could survive without successful breast feeding. Thus, infant growth is less of a priority than adequate preparation for lactation, and a mother who is inadequately nourished will continue to deposit fat even though fetal growth is slowed.

For the fetus to grow properly, the mother's metabolism must adapt not only in early pregnancy so that enough maternal blood will circulate through the placenta but also in middle and late pregnancy so that enough fat will be deposited to insure an adequate ability to lactate. To accomplish this second goal, another series of adaptive changes usually takes place. In particular, the mother's appetite increases and she begins to consume more food. Moreover, certain changes occur in her gastrointestinal tract, resulting in the more efficient absorption of a number of specific nutrients, including iron and calcium. (As we shall see, the fetus needs these substances in particularly large amounts.)

When food is abundant these adaptive changes work extremely well.

WHAT'S NEXT?

Get A Sample Issue And Find Out!

NEXT is an exciting new magazine that looks into the future — your future. Not a science magazine, or a science-fiction publication, NEXT brings you a considered look at what the experts think your life will be like in 2 years, 5 years, 10 years and beyond.

What you'll find in NEXT will fascinate you, for, as you'll see, the world is on the brink of far-reaching changes that may touch every phase of your life — your health, your job, where and how you'll live, how you'll travel, your pocketbook, your social life, your political beliefs, even what you'll eat and where you'll spend your vacation.

NEXT is written for the general reader — concise, lively, provocative, without technical jargon. And every issue is filled with forward-looking articles such as: How We'll Soon Control The Weather; New Cures for Anxiety and Depression; How You *Can* Obtain Financial Security; The New Sexual Morality; Tomorrow's "Beautiful People" — Who They'll Be; How You'll Shop By TV; and The Ultimate Solution to Inflation.

But why not see what's next for yourself? You can start a subscription to NEXT by mailing the coupon below. What's more, after your first issue, if you wish, you may cancel and owe nothing; so you've got nothing to lose.

NUNKO

When food is scarce, however, fetal growth is retarded. For example, in 1945 during the famine imposed by the Nazis in Holland, birth weight dropped significantly. Today in several rural Guatemalan villages average birth weights are noticeably low and studies have shown that they can be made to rise significantly by increasing the amount of food available to pregnant women.

Data such as these have led to a reevaluation of feeding practices during pregnancy and a series of recommendations that are quite different from those of only ten years ago. Doctors now advise that a woman consume enough calories to gain at least twenty-five pounds during the course of pregnancy. This can be determined by studying pregnant women who are neither urged to eat nor discouraged from eating and totaling the average weight gained as a result of the various maternal adaptations to pregnancy and the average weight of the fetal components and the placenta. More precisely, the uterus and breast tissue increase about one and a half pounds each; the increased maternal blood volume accounts for more than one pound; and the mother deposits ten to twelve pounds of fat. Thus the maternal adaptation accounts for about fourteen to sixteen pounds. The fetus weighs seven to eight pounds; the placenta, one to two pounds; and the amniotic fluid, which bathes the fetus, about one pound. The fetal compartment therefore represents nine to eleven pounds, making a total weight gain of twenty-five pounds.

Left to their own devices, most women do gain about twenty-five pounds during pregnancy, and statistics show that a normally nourished woman with a weight gain of twenty-five pounds can expect to produce an infant of about eight pounds. It should be noted that women who are underweight prior to pregnancy need to gain more than twenty-five pounds to produce an infant of comparable size, whereas women who are overweight prior to pregnancy, although able to gain somewhat less weight, must still gain a minimum of about fifteen pounds. The crucial element involved in this weight gain is calories. If the number of calories consumed daily is increased by 300 to 500, a twenty-five pound weight gain will result.

Why are we so concerned with adequate fetal size? Statistically, an infant has a better chance to survive and develop normally after birth if its birth weight is not low. Some statistics in the United States illustrate this point dramatically. The United States has only the eighteenth lowest rate of infant mortality in the world. In other words, an infant born in seventeen other countries (including Japan, Australia, and the German Democratic Republic) has a better chance to survive than one born in the United States—not a record to be proud of.

Most of the high rates of infant mortality are found in the poorer segments of the U.S. population, particularly among blacks. In some groups, infant mortality may be two to three times as high as among middle-class populations. But pound for pound, the poor baby does as well as the rich baby; black babies do as well as white babies. The difference in mortality can be entirely explained by the fact that babies from these disadvantaged groups weigh on the average half a pound less at birth than middle-class babies. Theoretically at least, if we could raise the average birth weight in this portion of the population by a half pound, we could erase the difference and significantly reduce our overall infant mortality. Poor maternal nutrition is certainly one of the many factors contributing to this low birth weight.

Thus the first and most important dietary recommendation for pregnant women is to increase their food intake so that the number of calories they consume daily increases by 300 to 500. From the standpoint of fetal growth, the source of these calories is not important. For example, in the study in Guatemala previously mentioned, when 20,000 extra calories were supplied throughout the course of the pregnancy, birth weight increased by nearly one pound. Whether the source of those calories was primarily protein or carbohydrate made no difference—a surprising finding since protein is essential to enable an infant to build new tissues. Recent experiments with animals may provide an explanation.

Rats fed a restricted diet have smaller pups at birth, and supplementation with either protein or carbohydrate returns pup size to normal. The composition of the mother's body changes markedly, however, depending on which type of supplement is used. If protein is supplied, the composition of the mother's body remains essentially normal for pregnancy. If carbohydrate is the sole source of the extra calories, however, maternal muscle tissue breaks down to supply the amino acids that would have been supplied by the dietary protein. In other words, a sufficient number of calories from any source will allow the mother to make the adaptations necessary to support the fetus, but unless protein is supplied, the fetus will derive amino acids from the mother's body. In this situation the fetus does become a parasite. For that reason it is indeed important for a pregnant woman to include a significant amount of protein in the foods with which she supplements her normal diet.

The present recommendation is that a pregnant woman increase her daily intake of protein by thirty grams. If the mother is on a reasonably balanced diet, this can be accomplished by simply increasing the amount of food she consumes. Certain specific nutrients are required in particularly large amounts in pregnancy, however, because of the special demands of the mother, the fetus, or both. These are the minerals iron and calcium and certain vitamins such as folic acid and vitamin B_6.

Iron is an integral part of the hemoglobin molecule and is therefore an essential component of blood. With the expansion in the volume of maternal blood, more iron is needed by the mother. Moreover, the fetus must manufacture its own blood supply—a supply that increases with fetal growth; hence large amounts of iron are needed by the fetus as well. Iron is normally present in only marginal amounts, however, and although iron is absorbed much more efficiently during pregnancy, in the past when the mother's intake of food was limited, iron intake had to be supplemented to prevent deficiency. Even now that the mother's food intake is being increased, supplementation during pregnancy is advisable unless special care is taken to consume iron-rich foods (for example, red meats, fortified grain products, beans, and dried fruit).

Calcium is necessary for proper development of the fetal skeleton and therefore is required in increased amounts during pregnancy. Supplementation is not usually necessary, however, since the mother's absorption of calcium from foods is markedly increased. (But because dairy products are an important source of calcium, a woman following a strict vegetarian regime during pregnancy may wish to take both calcium and iron supplements.) On the other hand, cal-

cium absorption depends in part on the amounts of other nutrients in the diet. For example, phosphorus has an important effect on calcium absorption; the higher the concentration of phosphorus in the mother's diet, the less calcium is absorbed. One major source of phosphorus in the American diet is certain types of carbonated soft drinks. Therefore, it is a good idea for a pregnant woman to limit her intake of those drinks.

One nutrient for which the increased requirement in pregnancy cannot be satisfied by a balanced increase in the amount of food consumed is folic acid, a vitamin necessary for cell division. The American diet barely satisfies the body's normal demand for this vitamin. In fact, folic acid deficiency is among the most common of vitamin deficiencies. During pregnancy, when both the uterus and the mother are manufacturing many new cells, supplementing the intake of folic acid is advisable unless special care is taken to consume foods rich in the vitamin. Special attention must also be paid to providing the fetus with a sufficient amount of vitamin B_6 (pyrodoxine). This vitamin is generally available in a normal diet, but in women who were on contraceptive pills for a long time prior to pregnancy, B_6 stores may be depleted and, at least early in pregnancy, supplementation may be warranted.

If we have learned anything about pregnancy in the past decade, it is that maternal nutrition and maternal weight gain during pregnancy will directly affect fetal growth. During pregnancy the mother must prepare herself so as to insure both the survival of the fetus and the survival of the infant after birth. To put it simply, poor nutrition interferes with these preparations and serves to retard the growth of the fetus. Thus mothers should eat more and gain more than was recommended in the past. For most women, just following the dictates of their appetites will result in the required minimum gain of twenty-five pounds. In this way they will allow their fetus to grow properly and at the same time prepare themselves adequately for the period of lactation that may follow.

Myron Winick is the director of the Institute of Human Nutrition and a professor of nutrition and pediatrics at the College of Physicians and Surgeons at Columbia University.

The Solar Shrink

Whether the sun is now—or ever has been—shrinking is a matter of dispute

by Stephen P. Maran

"Our wishes lengthen as our sun declines," wrote the English poet Edward Young (1683–1765). A few astronomers now believe that the sun is indeed declining or, more specifically, that it is shrinking, and they have revived an almost-forgotten controversy on the subject.

Obviously, no dramatic change is under way on the sun or we would all know about it, since the amount of light and heat reaching the earth depends on the size and temperature of the sun. If the sun pulsated noticeably, alternately shrinking and swelling like the variable star Mira, for example, there would be correspondingly radical trends in the earth's weather. The possibility remains that the sun may be shrinking slowly, with imperceptible immediate effects. However, even a slight but continuing change would eventually be reflected in a detectable climate change on the earth.

The current controversy was ignited in 1979 by two Boston-area researchers, John A. Eddy, then with the Center for Astrophysics in Cambridge, Massachusetts, and Aram Boornazian, with the private research firm of S. Ross and Company. But the debate goes back at least to 1809, when the great German mathematician and astronomer Karl Friedrich Gauss disputed a report that the sun's size had decreased during the latter half of the eighteenth century.

The evidence Gauss took issue with, like much of the evidence in the current controversy, consisted of direct measurements of the diameters of telescopic images of the sun. The alleged shrinkage under consideration today is so small—amounting at most to a decrease of a few feet per hour in the 865,000-mile solar diameter—that finding it depends on very small changes in the measurements of the images from year to year and decade to decade. Nevertheless, the solar image is blurred by our dusty and turbulent atmosphere, and critics claim that the reported trend may be due to changes in the telescopic equipment or in the atmosphere or to switches in the observing astronomers. In fact, analyses of solar-diameter measurements made at different observatories yield different results.

Some statisticians have found a shrinkage in the measurement data, some have found none, and some have claimed to detect gradual up-and-down trends in the solar diameter, as though the sun *were* pulsating like Mira, albeit by a vastly smaller amount and over a much longer period. The claimed periods, depending on which report you read, include ones of eleven years (the length, incidentally, of the sunspot cycle) and of twenty-two years (the length of a related phenomenon called the solar magnetic cycle). In view of the conflicting reports, about the only thing we can conclude at the present time is that the direct diameter measurements do not provide unequivocal evidence for *any* change in the size of the sun. There are, nevertheless, indirect ways of gauging the solar diameter that may be less affected by changes in the observing equipment, the observing personnel, and the earth's atmosphere.

One way to check on any change in the size of the sun is to investigate the accumulated observations of the transits of Mercury. (The transits are the passages of that tiny planet in front of the sun, as seen from the earth. They occur about thirteen times per century.) During transits, Mercury looks like a black dot against the brilliant solar surface; by timing the duration of a transit, one can deduce the size of the sun. In April 1980, a physicist at the Massachusetts Institute of Technology reported that analysis of transit timings made from 1736 to 1973 showed no solar shrinkage, although the data were capable of revealing a shrink rate six times smaller than had been claimed by Eddy and Boornazian.

Observations of eclipses of the sun represent another source of indirect information on the solar diameter. Surprisingly sensitive determinations can be made from very simple observations of eclipses. The size and orbit of the moon are known with high precision, as are the orbit of the earth and the earth's distance from the sun. Thus, it should be possible to calculate the circumstances of a solar eclipse with considerable accuracy. The calculations can then be compared with actual observations. For example, if the sun were larger than assumed, then the extent to which it is covered by the moon would be diminished, and the umbra, or shadow of the moon cast on the earth during a solar eclipse, would be narrower than expected. As the umbra moves across the earth, it traces out the "path of totality." If the sun were smaller than assumed in the calculations, the path would be wider than was computed and the duration of totality witnessed by a fixed observer on, say, the center line of the path would be longer than predicted.

In fact, an account of a sixteenth-century eclipse was used as an argument for the validity of solar shrinkage by Eddy and Boornazian, who also found an apparent decrease in the direct measurements made during the years 1836 to 1953 at the Royal Greenwich Observatory in England and from 1846 to 1950 at the U.S. Naval Observatory in Washington, D.C. They cited a description of the eclipse of April 9, 1567, written by the Ger-

man mathematician Christopher Clavius. Clavius, after whom a huge crater on the moon is named, observed the eclipse from Rome. Despite modern computations that indicate that this eclipse should have been total—although barely so—Clavius found that "a certain narrow circle was left on the Sun, surrounding the whole of the Moon on all sides." He apparently did not mean the solar corona, which resembles a broad patch of light around the sun during a total eclipse, and he was familiar with what to expect since he had studied an earlier total eclipse in 1560.

A bright ring of light is seen in an annular eclipse, that is, one that is not total because the moon is too far out in its elliptical orbit to block out the whole sun. Eddy and Boornazian argued that the 1567 eclipse was annular for a different reason, namely, that the sun was bigger in 1567 than allowed for by the computations, which are based on the modern value of the solar diameter.

Having witnessed several total eclipses of the sun myself, I was impressed by the above argument. In particular, I found it hard to accept a countersuggestion proposing that Clavius's "circle" consisted of light from the bright innermost zone of the solar corona. No part of the corona has ever seemed bright enough to me to be mistaken for a part of the far more intense solar surface. However, there is an explanation of what Clavius saw that does not require so exotic a phenomenon as a shrinking of the sun. According to John Parkinson, an experienced solar astronomer at University College, London, it is not sufficient to regard the edge of the moon as a circle of a certain size when you calculate the circumstances of a *barely* total eclipse. In such cases, you must allow for the topographic high and low spots around the lunar periphery.

Where there is a low spot on the moon's edge, a bit of the bright solar surface may still shine through, although the eclipse is supposedly total. This phenomenon occurs for only an instant during an ordinary total eclipse, either just before or just after the phase of true totality. Eclipse viewers call these momentary bright spots "Baily's beads," after a nineteenth-century English astronomer. Parkinson reports that a recalculation of the 1567 eclipse, which takes the hills and valleys of the moon into account, has been done at the Royal Greenwich Observatory. The results reveal that the eclipse would have featured an extreme case of Baily's beads, with a great many bright spots, like an outbreak of solar measles, all around the moon's edge. Further, the bright spots would have persisted throughout the phase of totality, so that in a sense the eclipse was not truly total. This string of Baily's beads might fairly have been called a "circle" by Clavius, who viewed the eclipse without a telescope.

There remains one report of solar shrinkage for which there is not yet any seriously conflicting evidence. This finding, by five American, Australian, and English astronomers led by David W. Dunham of the Computer Sciences Corporation in Silver Spring, Maryland, and Sabatino Sofia of the Goddard Space Flight Center in nearby Greenbelt, is based on determinations of the width of the path of totality at solar eclipses in 1715, 1976, and 1979. The 1715 eclipse was viewed from many locations in southeastern England at the behest of Edmond Halley of comet fame. The Dunham and Sofia analysis of the English reports shows exactly where in the Kentish countryside the northern and southern edges of the path of totality went.

There is no measurable difference in the determinations of the solar diameter from the 1976 and 1979 eclipses, which is hardly surprising given the short interval between the two events. However, the width of the path of totality in 1715 implies a very slightly larger sun. Taken at face value, there was a decrease of about 400 miles in the size of the sun over 264 years. Although this shrinkage is so small as to be near the limit of detectability in the available data (but too small to be ruled out by the transit of Mercury measurements), it nevertheless cannot have been under way over truly long periods of time. In fact, a shrinkage at this rate would reduce the sun to nothing in less than one million years. More likely, if the claimed shrinkage effect is indeed real, the sun must periodically reverse itself and slowly enlarge again. At least, let's hope so.

JACK DANIEL SQUARE GLASS SET

Mr. Jack Daniel was the originator of the square bottle for his whiskey and always wanted to have a matching square glass. Well, here it is! This hefty square glass (each weighs 14 ounces) is the perfect companion to a bottle of Mr. Jack's finest. The inside is rounded to make drinking a pleasure and the original design is fired on for good looks and durability. My $15.00 price for a set of 4 glasses (8 oz. capacity) includes postage.

Send check, money order, or use American Express, Visa or Master Charge, including all numbers and signature.

(Tennessee residents add 6% sales tax.) For a color catalog full of old Tennessee items and Jack Daniel's memorabilia, send $1.00 to above address.

Enter the world of Questers nature tours.

When you travel with Questers, you have the advantage of our knowledge of the travel world And our experience of the natural world We are travel professionals And our only tour program is Worldwide Nature Tours.

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers rain forests, mountains, and tundra seashores, lakes, and swamps of the regions we explore At the same time, we include the more usual attractions in touring—the cities, archaeological sites, and people

The current Directory of Worldwide Nature Tours describes 29 tours varying from 9 to 36 days and going to virtually every part of the world Included are The Amazon, Peru, Patagonia, Galapagos, Hawaii, Alaska, Death Valley, Everglades, Ladakh, Sri Lanka, Iceland, Scotland, Greece, Australia, and New Zealand Tour parties are small, the pace leisurely, and itineraries unusual

Celestial Events

by Thomas D. Nicholson

The Moon Evening moonlight will be significant about mid-January and again in mid-February, when the moon is up for most of the night. The moon is a morning object until it is new on January 6. The first view of the young crescent will be on about January 9, followed by first-quarter on the 13th, full moon on the 20th, and last-quarter on the 27th. The moon will be new again on February 4, and first-quarter on the 13th. Perigee moon (nearest the earth) is on January 15 and February 8; apogee (farthest from the earth) on January 27. The light cast by the full moon in January is exceptionally bright and intense because the moon climbs so high in the sky during its nightly passage.

Stars and Planets Only Mercury and Mars are evening planets but neither is well placed for viewing. The bright planets are still morning stars but Venus is well past its best. Jupiter and Saturn are in good position. Although morning objects (above the horizon at sunrise), they rise about two hours before midnight and are high in the south by dawn. The two planets will be extremely close to each other this winter in the constellation Virgo, not far from its brightest star, Spica. Jupiter will be easiest to find because of its extreme brightness (surpassed at night only by Venus and the moon). The two planets come this close only about once every twelve years or so when Jupiter passes the slower Saturn. But one year in every hundred or more, the effects of retrograde motion cause Jupiter to pass Saturn three times within just a few months. This is the year. The first conjunction will occur on January 14 (Jupiter moving left past Saturn), the second on February 19 (Jupiter moving to the right-retrograde), and the third on July 30 (Jupiter moving to the left again).

January 1: The earth is at perihelion (nearest the sun) on New Year's Day, approximately 147,093,000 kilometers (91,400,000 miles) from the sun, some 5 million kilometers (3 million miles) closer than in July.

January 4: You can see Venus low in the east this morning, rising shortly after the waning crescent moon at about 4:30 A.M.

January 6: The latest sunrise of the year occurs. Sunset is now fifteen minutes later than it was in December, but the time of sunrise changes more slowly from mid-December to mid-January.

January 14: Jupiter is in conjunction with Saturn, moving from Saturn's right to its left.

January 16: The bright star near the moon is Aldebaran, in Taurus.

January 19: Saturn begins its retrograde (westward) motion relative to the stars.

January 20: A penumbral, or partial, eclipse slightly dims the brightness of tonight's full moon.

January 23–24: The waning gibbous moon is close to Jupiter and Saturn from the time of rising (about 10:30 P.M. on the 23rd and 11:30 P.M. on the 24th).

January 25: Jupiter begins its retrograde motion, and both Jupiter and Saturn can be seen shifting slowly away (to the right) from Spica.

January 31: Mercury is at its greatest distance (elongation) to the sun's left, leaving it above the horizon after sundown. For a week or so before and after this date, the planet will be low in the west during late twilight.

February 3: The crescent moon is near Venus again this morning, but both are probably too low to be seen in the dawn.

February 4: An annular solar eclipse (a ring of the sun remains visible around the moon at mid-eclipse) occurs in the South Pacific Ocean.

February 12: The moon is near the star Aldebaran (in Taurus) again tonight.

DISCOVER SPAIN, PORTUGAL AND FRANCE

with the American Museum of Natural History

JUNE 23 TO JULY 8, 1981

Discover with Dr. Thomas D. Nicholson, Director of the Museum, and six other scientists, all experts in their fields, the rich cultural heritage, beautiful shores and countryside of Western Europe.

Enjoy the grandeur of the Sierra Nevada, superb Moorish palaces and gardens of Granada and Seville, Barcelona's art and architecture, the famous monasteries and monuments of Lisbon, vine-clad hillsides surrounding Oporto, the pilgrim shrine of Santiago de Compostela, the Huguenot tradition of La Rochelle. Visit splendid parish closes in the rich Brittany countryside, awesome Mont St. Michel, famous medieval Rouen as the goal on a scenic cruise up the Seine. Explore coasts and valleys, fields and highlands profuse with shore and land birds, fertile with blossoming flowers.

Experience the educational holiday of a lifetime with compatible members and friends of the Museum. Travel aboard the intimate and comfortable m.t.s. Orpheus and see the superb scenery from a vantage point that most visitors can never have.

Operated for the Museum by W.F. & R.K. Swan.
The Orpheus is registered in Greece.

Kurt Waldheim on Asian Peoples

On October 16, 1980, the American Museum of Natural History celebrated the opening of the new Gardner D. Stout Hall of Asian Peoples. Following an introductory speech and presentation by Museum president Robert G. Goelet, Kurt Waldheim, secretary-general of the United Nations, gave a short address. We have reproduced his speech here in full. In it he outlines his view of the significance of the hall and what it symbolizes for world understanding and peace.

New York is one of the great cultural centers of the world and, as the host city of the United Nations, a political center of international life as well. The Gardner D. Stout Hall of Asian Peoples at the American Museum of Natural History makes a significant addition to the city's resources for broadening the cultural awareness of its residents and visitors.

I find it most appropriate that the theme of this exhibition should be the peoples of Asia. This lends it a special appeal and fascination. Of all continents, Asia is not only the largest; it also contains a greater variety of ethnic groups, traditions, and languages than any other. All of the great world religions originated in Asia. Some of the oldest civilizations flourished on that continent. In a broad sense, therefore, Asia represents more than Asia. Called the Mother of Civilization, it stands for a large part of the entire human heritage.

Once we realize the value and meaning of this Asian part of our collective inheritance, we can hardly question the necessity of overcoming the great ignorance about Asian peoples that prevails not only in Europe, the Americas, and Africa but also, to some extent, in Asia itself. Two facts of cultural history explain this ignorance. First, owing to Europe's domination of the globe from the eighteenth to the middle of the twentieth century, Asians had perforce to learn much more about Europe and even the Americas than Europeans and Americans felt they needed to know about Asia. Secondly, Asia itself, which stretches from Turkey east to Japan and from Siberia south to Sri Lanka, is so large and multitudinous that, historically, those who lived in one part of it knew little about those living in another. The Hall of Asian Peoples can, therefore, offer as much edification to an Asian as to a non-Asian.

May I now turn to the broad significance of cultural undertakings such as this exhibition. For the first time in history, the human race is coming to understand that it constitutes a single community and inhabits a world that is indivisible. All of us, of course, retain and take pride in our respective national and cultural identities. Over and above these affiliations, however, we have all become citizens of one world.

A certain amount of knowledge about the different peoples of the globe and their traditions should now be an essential part of the equipment for this citizenship. We now know more than ever before how human cultures have interacted and interpenetrated throughout history. In older times, before modern communications and the growth of a variety of academic disciplines, a person who studied two cultures would be absorbed by their differences. Now, without losing sight of the specific features of each, we are equally fascinated by their points of resemblance. To detect the parallels—the elements of correspondence—between different societies is an invigorating exercise. More important than that, this exercise serves to rid us of the influence of those myths of cultural superiority that give rise to ethnic prejudice and cultural arrogance.

We may be unhappy about much in our world today, but here is one fact at least that signifies real, undeniable progress: In our age there exists a far more sympathetic comprehension of the world's diverse societies, a greater respect for cultures and peoples different from one's own, than was ever the case before. This includes an interest in traditional ways of life unaffected by modern technology. Walls that separated cultures and inhibited their mutual understanding are steadily being dismantled. I feel that this broadening of sympathies, this liberation from prejudice, represents a great accomplishment of humanity that will help to make its future brighter than its past.

This is not only a moral and intellectual resource. It is a matter of great political consequence as well. This is apparent in numerous ways; I choose but one example. Let us compare the world of the United Nations with that of the colonial era. Colonialism was based on the assumption that civilization as such meant West-

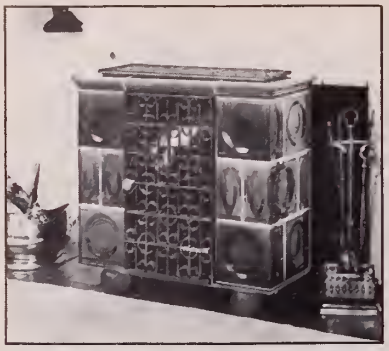
"It looks like a fun-house mirror, but it gave Gulf a clear look at the future of solar energy."

"There's more to solar energy than the flat black solar collectors you see on the roofs of houses," says Staff Engineer Julien Reynaud. "For instance, this solar concentrator we developed here at General Atomic. It looks like a fun-house mirror, but it can heat flowing liquids to temperatures up to 1100°F.

"General Atomic is working hard to determine how much commercial power you can extract from sunlight."

"There are other technologies being developed by General Atomic, which is 50% owned by Gulf Oil, to make solar energy commercially practical. Our newest solar projects include a multiple-effect thin-film distillation process that can produce a lot of distilled water using low-grade heat sources; and polycrystalline photovoltaic cells for converting sunlight directly into electricity.

"There's still a long way to go. We'll be into the next century before sunlight supplies more than 5% of this country's total energy requirements. But there has been progress. Solar energy is already working in some factories, heating water, bleaching textiles, drying lumber.



"Of course, solar energy works best where it's sunny, dry, and with almost no air pollution. But wherever it works, it frees up precious fossil fuels for use somewhere else.

"Gulf's research in solar energy is one part of our overall commitment to energy for tomorrow."

Gulf

Gulf people: energy for tomorrow.

Gulf Oil Corporation

Now, seven beautiful ways to keep warm

At last — a superbly efficient woodburning stove beautiful enough for your home. And now in your choice of seven decorator tile colors!

The WESO Ceramic Tile Stove employs both convection and radiant heat to surround you with gentle all-over warmth. The fire burns all night without tending — when the coals have finally died, the tiles continue releasing heat into your rooms.

The WESO burns both wood and coal and offers every efficiency feature you could ask for. It enhances the beauty of your home, where a black metal stove would be rudely out of place.

Enclosed is $1. Rush me your literature showing the WESO CERAMIC TILE STOVE in all 7 tile colors — plus details about WESO's new COALBURNING STOVE — and shipping schedule for winter delivery

ern civilization; other societies were regarded as civilized only to the degree that their systems or institutions approximated the Western pattern. In other words, the world was divided into civilized peoples and what were called "lesser breeds." We have come a long way from that kind of thinking—so long, in fact, that it is hard to believe that such prejudice prevailed until only a few decades ago.

One of the basic principles of the Charter of the United Nations is that of the sovereign equality of all members of the organization. This is not just an abstract principle; it is an operative fact governing the actual working of the different organs of the United Nations. What lies behind it is nothing short of a revolution in attitudes, political as well as cultural. Decolonization, the greatest development of our century, is a product of this revolution. The more we absorb all the implications of this change, the better will international understanding and cooperation grow and the greater will be our capacity to manage our problems.

This is not the occasion for me to talk about the world's problems. We all know that some of these problems are currently causing us a great deal of anxiety. I do not underestimate their gravity. Undoubtedly, we are passing through a very difficult phase of international relations. Our immediate problems relating to peace and security are, of course, a different matter; but as far as our long-range problems are concerned, there is a certain positive element in the very fact of their being listed on the world's agenda.

Their nature bears an essential relation to the understanding of the world and of peace that the United Nations has worked to promote. Take the problems of reducing poverty and ignorance in the world. We are addressing our attention to them because we consider peace to mean something larger and regard the world as more unified than people did before the United Nations was founded. If we did not believe—as we do—that peace is not stable unless it assures justice and secures progress for all, if we did not regard—as we do—our world as interdependent and therefore indivisible, we would not be concerned as much as we are, for example, by the delay in instituting a new international economic order. This does not mean

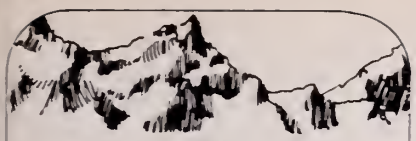
Dance Around the World

In a program geared especially for families, the Membership Office will present *A World of Dancing* with the Matteo EthnoAmerican Dance Theater on Sunday, January 18, at 2:00 P.M. in the Auditorium. Dances will include a comical mask dance from Japan, castanet dances from Spain, jigs and hornpipes from Ireland, and in a melding of East and West, a dance from India set to an American folk tune. Tickets are $1.00 for members, $4.00 for nonmembers. For ticket information call (212) 873–1327.

The Past Researched

The January Members' Program, *The Grand Canyon*, ties in with the Museum's current special exhibition, *Profiles of the Past*. Sidney Horenstein, curator of the exhibition, will use slides and film to discuss the natural history of the Grand Canyon, from its geologic past to the plants and animals that inhabit its rugged terrain today. The program will take place on Wednesday, January 21, at 7:30 P.M. in the Auditorium and is free for members; $3.50 for the general public.

Man and Nature



On the weekend of January 10 and 11, the Education Department is presenting a program of *Man and Nature Films*. Beginning at 2:00 P.M. in the Auditorium, three free films will be shown: *The Great Blue Heron, The Wolf and the Whitetail*, and *Last Stand in Eden*.

Workshops for Young People

January is registration time for the spring series of *Workshops for Young People*. Children in grades 4 to 7 can learn about the world of natural science through hands-on activities with Museum instructors in laboratories and in the field. Write the Department of Education for a brochure and application form.

Tribute to King

On Thursday, January 15, the Museum will celebrate the birthday of Martin Luther King, Jr. *La Rocque Bey Dancers and Drummers* will present a program of Caribbean music and dance, and other musicians will also perform during the evening. This free program begins at 7:00 P.M. in the Auditorium.

that we are being merely idealistic. Our beliefs are grounded on facts; our perceptions are pragmatic; what we seek are real necessities. But it does not signify that the frustrations and anxieties we suffer are those that arise at a higher level of international life than was ever attained before. This is the level humanity has risen to; to descend from it is no longer a practical proposition.

As in our international political dealings, so in our study and observation we must keep the thought always in our minds that no nation is an island unto itself and that all the world's peoples are neighbors who need to learn much from one another. I trust that this largest collection of Asian artifacts ever assembled outside Asia will not only impress the millions who are going to see it with the beauty of Asian art and crafts and the long and richly varied heritage of Asian societies but will also help to nourish the sentiment that all of us belong to one human family. Besides being a source of great enjoyment and instruction, let this exhibition serve as an instrument for better international understanding and, in this way, help to promote the cause of peace.

$1.75 per word; 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired. Occasionally, slight editing is required for clarity. Thank you!

Divine Plants

by Peter T. Furst

THE WONDROUS MUSHROOM, by R. Gordon Wasson. *McGraw-Hill Book Company, $14.95; 229 pp., illus.*
PLANTS OF THE GODS, by Richard Evans Schultes and Albert Hofmann. *McGraw-Hill Book Company, $34.95; 192 pp., illus.*

Two books by leaders in the study of plant hallucinogens have appeared within a few months of each other. One, by R. Gordon Wasson, gives us the first in-depth treatment of the sacred mushrooms of Indian Mexico and their cultural ramifications; the other, by Richard Evans Schultes and Albert Hofmann, covers the botany, history, ethnology, and biochemistry of the world's major psychoactive flora. All three writers have been associated for many years in common or parallel pursuit of a cultural phenomenon that we now know has respectable antiquity, reaching back thousands of years into prehistory, with wide geographical distribution (but centered on Middle and South America) and important implications for contemporary Western science and society.

Wasson is the pioneer ethnomycologist whose painstaking search for the identity of the ancient Indo-European plant deity *Soma* led him to *Amanita muscaria*, the sacred, inebriating fly agaric mushroom of Siberian shamanism and European folklore, an identification accepted by many, though not all, Vedic scholars. Schultes, Paul C. Mangelsdorf Professor of Natural Sciences at Harvard and long-time director of the Harvard Botanical Museum, forty years ago documented the divine Aztec hallucinogen *ololiuqui* as the seeds of the morning glory and has since made innumerable contributions to our knowledge and understanding of the rich psychoactive flora of the New World. Hofmann, coauthor of this work, is best known as the discoverer of LSD-25. But we are also indebted to him for the identification of the active compounds in the Mexican sacred mushrooms, the morning glories, and some other plants that Mexican Indians are certain possess the attributes of divinity. Not surprisingly, Wasson and Schultes played important roles in the direction of Hofmann's research in this area of chemistry; indeed, it was Wasson who collected sufficient seeds from two species of Mexican morning glories to allow Hofmann to bring his work to a successful conclusion. In 1960 he announced his startling discovery that the principal psychoactive compounds in morning glory seeds were nothing other than lysergic acid alkaloids, closely allied to his own synthetic LSD-25. It was the first time that such compounds had been identified in one of the higher plants, having been previously found only in such lowly fungi as ergot.

From morning glory seeds to the analysis of the magic fungi known to the Aztecs as *teonanácatl*, "flesh of the gods," was but a small step. Wasson again was the catalyst, but it was the famous French scholar Roger Heim who in his Paris laboratory succeeded in propagating specimens of Oaxacan mushrooms from which Hofmann isolated, for the first time, the natural agents chiefly responsible for their extraordinary psychic effects.

The Mexican "cult" of sacred mushrooms was first described by Spanish chroniclers in the sixteenth century. In the early twentieth century, William A. Safford, a leading U.S. botanist, rejected the story as implausible, suggesting that the Spaniards and their Aztec informants must have been talking of peyote, not mushrooms. (He also doubted the existence of hallucinogenic morning glories.) But in the late 1930s, several eyewitness accounts by reliable observers—the young Schultes among them—confirmed the veracity of the old reports that they were indeed mushrooms. The general public, however, remained unaware of all this un-

til Wasson described his own extraordinary experience as a participant in a divinatory rite involving the consumption of the sacred mushroom in the village of Huautla de Jiménez in the May 13, 1957, issue of *Life*. The article, unfortunately, resulted in a veritable invasion of the Indian highlands by seekers of instant nirvana through chemistry. Wasson has since written many times of the event, which he characterized as soul shattering and which totally reversed what he now recognized as culturally conditioned hostility to the fungal kingdom, especially its psychoactive members. In 1974 he published *María Sabina and Her Mazatec Mushroom Velada* (see review in *Natural History*, December 1975), a tour de force of modern ethnography. This book contained the complete text in Mazatec, Spanish, and English of María's prayer chants, part Christian but mainly native in origin, and her consultation, bemushroomed, with the sacred plant whose voice she, her patient, and the other Indian participants took to be that of Christ. Included with that remarkable book were four cassettes made from the original recording. Part of Wasson's new work is devoted to the 1955 experience, but his retelling is enriched by a fresh interpretation of the role of sacred mushrooms in Mesoamerican cultural history before and since the Spanish conquest. Along with Wasson I deplore the odd lack of response from anthropologists to his contribution, which to me seems crucial to understanding Native Middle American religion and the shamanic phenomenon as it survives in Mexico.

The book contains an analysis of the plant symbols carved on the famous statue of the Aztec god of flowers and rapture, Xochipilli, in Mexico City's National Museum of Anthropology. Schultes helped Wasson identify these plants, every one of which turned out to be one of the ritual intoxicants used by Mexican Indians, including tobacco, morning glory, *Heimia salicifolia*, sacred mushrooms, and possibly *poyomatli*, the flowers of a tree native to Veracruz and Oaxaca that were so highly esteemed by the Aztecs that they imported them over long distances.

Wasson's elucidation of the real meaning of the magnificent Aztec statue breaks entirely new ground in Aztec cultural history. Clearly the mushroom motif is central to the understanding of the god and of important aspects of Aztec religion. The mushroom motif is repeated on the deity's knees, the right forearm, the top of the head, and very prominently, on the base on which he is seated in a pose that suggests rapture, or ecstatic trance. Xochipilli, then, is more than the god of merriment and flowers—he is Lord of the "Flowery Dream," as the Aztecs so aptly called the ecstatic trance experience with the sacred psychoactive plants.

Some ten years ago, my own iconographic studies of hallucinogens in pre-Columbian art led me (also with the help of Schultes) to the identification of the morning glory, *Turbina corymbosa*, in the mural art of Teotihuacán, specifically at Tepantitla, but in the past I have been doubtful of Wasson's insistence of the presence there of sacred mushrooms. Now I am no longer so dubious—his case in this book for the mushroom in the murals and on some painted polychrome Teotihuacán pottery is much stronger than I originally supposed. But—and this is an important point—if what Wasson believes to be mushrooms really *are* mushrooms, they contain a significant message for the viewer. For they are all shown, not from above or in profile as they are elsewhere, but from below, featuring the juncture of the stem and the ribbed underside of the cap. Are we meant to see the mushrooms—as did the Indians' divine progenitors (or alter egos)—as the deities of earth and un-

derworld? Can this help us to identify the specific locale of the scenes in the murals: just which level of the multitiered Mesoamerican universe is being depicted here? If so, the mushroom motif, almost by itself, reveals the murals' subject matter to be the underworld, fertile womb of the maternal earth from whence originate moisture and fertility.

Wasson concludes his exploration with an overview of the historical record, from the time of the conquistadors to the present. He also gives us the most thorough discussion to date of the famous "mushroom stones" of highland Guatemala and Mexico and their relationship to the ancient use of the sacred fungi as early as the mid-first millennium B.C., a functional connection most authorities now accept. He is, however, more impressed than I with published arguments for a connection between the mushroom effigies and the sacred ball game. These stone replicas may have played some role in the game—really a religious ritual—but I doubt that any were ever used to mold hollow rubber balls. In fact, all the descriptions of the game, and all the archeological finds, demonstrate unequivocally that the rubber balls were solid, never hollow, and so heavy that the chroniclers speak of serious injuries if a player was hit in a sensitive part. But these are minor flaws in a work whose flights of intuition are generally informed by painstaking scholarship.

Wasson's advocacy of a recently coined term, "entheogen" (God within us), in place of the more popular, but value-laden, "hallucinogen," because entheogen more nearly approximates "the rich cultural resonances evoked by the substances," is nicely complemented by the title of Schultes's and Hofmann's *Plants of the Gods*. This is a truly encyclopedic examination of the psychoactive flora of the world, profusely illustrated on every page in black and white and with more than a hundred color plates. There are introductory chapters on the definition of plant hallucinogens and their place in the plant kingdom, phytochemical research to date on sacred intoxicating species, geographical and botanical distribution and use (with a very clear map), and a most useful 29-page illustrated plant lexicon covering no fewer than ninety-one species with known or presumed psychoactive properties. This is followed by specific discussions of fourteen major Old and

New World species and their cultural roles. The lexicon is ordered alphabetically by genus name, and all have fine color illustrations, mostly hand-drawn but a few photographic, to facilitate identification in the field. A word of caution (which the publishers might have displayed more prominently): although most hallucinogenic plants are neither habit forming nor have lasting detrimental effects on the body, a few can be dangerous if ingested (*Datura*, for example, and some members of the Leguminosae, such as *Sophora secundiflora* of the "Red Bean Cult" of the Southern Plains Indians). Also, neophytes may find it difficult to distinguish some entheogenic mushroom species from highly toxic ones.

The lexicon is followed by a brief discussion of users of hallucinogenic flora and a convenient fifteen-page overview of plant use and effects, facilitating the confirmation or contradiction of claims made for a particular species. The section dealing with the fourteen major hallucinogenic plants properly leads off with a discussion of *Amanita muscaria*, whose use by shamans of the Eurasian forest belt may predate the early peopling of the Americas by hunters migrating from northeastern Asia, who may have arrived here prepared for a search of the environment for species with similar psychic effects.

In other chapters, the book deals with the "hexing herbs," particularly henbane, mandrake, and belladonna, which became famous in Europe in the Middle Ages; with *Cannabis*, a hardy multipurpose genus of Asian origin introduced into the Americas after the conquest and long exploited not only for its psychotropic properties but for its economic, nutritional, and medicinal values (most recently in the treatment of glaucoma and of the extreme nausea that accompanies chemotherapy); and with the curious ergot (*Claviceps purpurea*), a fungal blight of Old World rye grasses responsible for many of the bizarre epidemics of hallucinations and poisonings, often fatal, that swept Europe in the Middle Ages and, less certainly, for the sublime ecstatic experience known as the Eleusinian mysteries of ancient Greece.

Among the many other plants covered in subsequent chapters is peyote, which has a natural range restricted to north-central Mexico and the Rio Grande valley of Texas, but whose use as a sacrament by some 250,000 Indian adherents of the Native American Church, from the Mexican border to the Canadian Plains, makes it the most widely used entheogen of all.

Schultes's career as the ranking authority on New World hallucinogens began, in fact, with peyote. His introduction to the ethnobotany of hallucinogens dates back to 1936, when, as a senior in biology at Harvard, he accompanied Weston La Barre, then a doctoral candidate in anthropology at Yale, to the Kiowa Reservation in Oklahoma to study the nature and culture of peyote. The peyote chapter draws heavily on accounts and illustrations of its use among the Huichol Indians of Mexico and by Native American members of the so-called peyote church.

A final chapter deals with some recent medical applications of hallucinogens, particularly LSD in the psychotherapeutic treatment of terminal cancer patients, to free them from the fear of death and, to some degree, from the perception (although not the reality) of pain. This chapter presumably had some contributions from Joan Halifax, a medical anthropologist with direct experience in such treatment, who researched and wrote many of the captions and also participated in the conception and design of the book.

With respect to captions, the deity depicted with the stylized morning glory plant in the Tepantitla mural on pages 160–61 is, of course, not an "Aztec Mother Goddess," but a mother goddess of the people of Teotihuacán, inasmuch as the mural dates from the early to mid-first millennium A.D., the height of the great Teotihuacán civilization. The Aztecs did not arrive in the Valley of Mexico until the thirteenth century A.D., centuries after Teotihuacán had been abandoned and had fallen into ruin. Finally, notwithstanding the unquestioned authority of Schultes and Hofmann, one misses footnotes; the identification of sources other than their own research would not have detracted from this handsome and valuable, if (understandably) expensive, addition to the literature. For the sake of my students, I hope for an early paperback version.

Peter T. Furst is professor of anthropology at the State University of New York at Albany and author of the books Flesh of the Gods *and* Hallucinogens and Culture.

Join Us in the Grandest Adventure of All

Now you can join some 50,000 adventurers who subscribe to ARCHAEOLOGY. In the 1980s, you will visit "digs" from Australia to South America, from Alaska to the Far East and everywhere in between. On these round-the-world journeys of exploration, you will have professional archaeologists as your guides—men and women intimately involved with the projects, writing in a clear, concise, easy-to-read manner. Through the many magnificent full-color photographs, your home will become a veritable gallery of the most exquisite art and artifacts of the past.

- Visiting Archaeological Sites—A twice-a-year feature that brings you news of actual archaeological sites that welcome visitors, both in North America and around the world. Included are dates and hours, what to look for, how to get there, whether accommodations are available and who to write for further information.
- Archaeology News—Important excavations and newly-discovered objects worldwide, as well as reviews of exhibitions.
- Current Exhibitions—What to see in museums in North America and abroad.

Additional Reading

British Museum (p. 38)

An account of the life of John Edward Gray (1800–1875) and Albert Gunther (1830–1914), A. E. Gunther's *A Century of Zoology at the British Museum Through the Lives of Two Keepers* (London: William Dawson and Sons Ltd., 1975) is also a record of zoology and natural history in the late nineteenth century, ending with a chapter on "The Problem of Darwinism." G.R. DeBeer's *Sir Hans Sloane and the British Museum* (New York: Arno Press, 1975) is a detailed biography of the physician, naturalist, and great collector. *The Life of Richard Owen* (London: Gregg International, 1970) is a biography of the famous naturalist written by his grandson, Rev. R. Owen. Originally published in two volumes in 1895, this book includes an essay by T.H. Huxley, "Owen's Position in the History of Anatomical Science." According to author J.M. Cook, his illustrated essay, *The British Museum* (New York: Praeger Publishers, 1972), is "a case study in aesthetic politics" and an attempt to "explain the relation between the British Museum as an institution and the British Museum as a piece of architecture." Cook describes E. Edward's *Lives of the Founders of the British Museum* (New York: B. Franklin, 1969, reprint of the 1870 edition) as "a mine of information" that is "ponderous but invaluable." In his introduction to *The Journal of a Disappointed Man*, by W.N.P. Barbellion (New York: George H. Doran Co., 1919), H.G. Wells called it "the diary of an intensely egotistical young naturalist," whose many accomplishments included securing an assistantship at the British Museum (Natural History). J.S. Weiner's *The Piltdown Forgery* (Oxford: Oxford University Press, 1955) covers an important segment of the British Museum's history. Since its advent, the museum has published and revised a number of scientific papers, guides to the departments and exhibitions, and handbooks. From 1927 to 1936, the museum published *The Natural History Magazine.*

Acadians (p. 48)

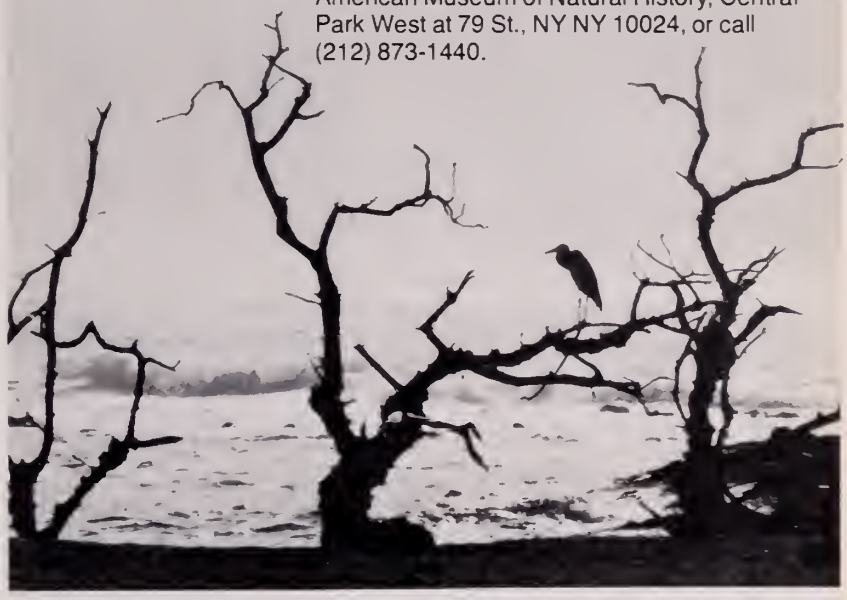
The Cajuns: Essays on Their History and Culture, edited by G. Conrad (Baton Rouge: The Lafayette Press and Center for Louisiana Studies, 1978), is a major collection of essays on Acadian life. Short and readable, J.D. Casanova and A. Landry's *America's French Heritage* (Quebec City: Quebec's Official Publisher, 1976) includes information about the Acadians. Two Louisiana-based scholars, M.P. Rieder and N.G. Rieder, have privately published a number of works on the genealogical records of the Acadians, including *Belle-Ile-en-Mer Registers with the La Rochette Papers*, volume two of a series entitled "The Acadian in France." Their work can be obtained by writing to them at 1457 Poinsetta Drive, Metairie, Louisiana 70005. Also privately published are the genealogical studies made by A. J. Robichaux, *Acadian Marriages in France*, available from him at 532 Manhattan Boulevard, Harvey, Louisiana 70052. *The Acadians, Creation of a People* (Toronto: McGraw-Hill Ryerson, 1973) is a short essay on Acadian history by N.E.S. Griffiths. A history covering the deportation and exile of Acadians is D.J. LeBlanc's *The Acadian Miracle* (Lafayette: Evangeline Publishing Co., 1966).

Mountain Goats (p. 58)

Hoofed Mammals of the World, by illustrator U. Mochi and mammalogist T.D. Carter (New York: Charles Scribner's Sons, 1971), depicts more than 290 ungulates; a chapter on the goat-antelope includes information about the Rocky Mountain goat. The result of a three-year study, G.B. Schaller's *Mountain Monarchs* (Chicago: University of Chicago Press, 1977) is a comprehensive overview of the behavior, ecology, and taxonomy of mountain ungulates in the Himalayas. D. McCowan's *Animals of the Canadian Rockies* (New York: Dodd, Mead and Co., 1936) devotes pages 119–28 to the mountain goat. In "On the Rutting Behavior of Mountain Goats" (*Journal of Mammalogy*, November 1964, pp. 551–68), V. Geist discusses courtship and rut behavior and shows that mountain goats have evolved intense threat displays and reduced their fighting to a minimum. The significance of the goats' coat pattern is also explained. This article includes numerous sketches of goat postures, threat stances, and displays. "Winter Habitat Use by Mountain Goats," a two-volume report by J.W. Schoen (Juneau: Alaska Department of Fish and Game, October 1978; December 1979), assesses the home ranges and seasonal habitat requirements of mountain goats in southeastern Alaska. A twenty-three page description of mountain goat ecology and behavior that includes a bibliography is L.D. Hibb's "A Literature Review on Mountain Goat Ecology" (Colorado Department of Game, Fish, and Parks, and Colorado Cooperative Wildlife Reserve Unit, Special Report, no. 8, July 1966). For a brief, general portrait of the Rocky Mountain goat, see O.P. Breland's "The Mountain Goat" (*Audubon*, May–June 1954, pp. 112–13). V. Geist's *Mountain Sheep* (Chicago: University of Chicago Press, 1971), a study of behavior and evolution, includes some information on goats for comparison. Featuring approximately 200 color photographs, many outstanding, E.R. Ricciuti's *Wildlife of the Mountains* (New

York: Harry N. Abrams, Inc., 1979) is an exploration of some of the animals that inhabit mountains.

East China Sea (p. 70)



Oceanography in China, a report published by the National Academy of Sciences in April 1980, depicts the state of the Chinese oceanographic community from the end of the Cultural Revolution to the present. The most up-to-date, thorough review of Chinese oceanography, this work is available at a cost of $7.00 from the National Academy of Sciences Press, Washington, D.C. Highly praised, R. Terrill's *Mao* (New York: Harper and Row, 1980), is an account of Chinese society in the 1960s and 1970s. *Chinese American Interactions*, by J.K. Fairbanks (New Brunswick: Rutgers University Press, 1975), is a historical summary of the relations between China and the United States. H.W. Shen's "Some Notes on the Yellow River" (*Eos*, 1979, vol. 60, pp. 543–47) provides some interesting observations about human influence in the area. For abstracts of scientific articles on the East China Sea, consult *Oceanic Abstracts*. In 1979, this journal summarized ten articles about the morphology, hydrology, and taxonomy of the East China Sea. For background material in the field of marine geology, F.P. Shepher's textbook, *Submarine Geology* (New York: Harper and Row, 1974), is a good starting point. Other textbooks with basic information on continental shelves and plate tectonics are B.F. Mallory and D.N. Cargo's *Physical Geology* (New York: McGraw-Hill Book Co., 1979); J.A. Jacobs, R.D. Russell, and J.T. Wilson's *Physics and Geology* (New York: McGraw-Hill Book Co., 1974); and A.N. Strahler's *Principles of Physical Geology* (New York: Harper and Row, 1977).

The Taming of the Grain

North America's native grain, wild rice, has finally been domesticated

by Raymond Sokolov

Unmolested worked the women,
Made their sugar from the maple,
Gathered wild rice in the meadows
Longfellow,
The Song of Hiawatha

Sitting in Cambridge, Massachusetts, in the big Brattle Street house his father-in-law had given him, Longfellow presumed to write an epic of Indian tribal life in northern Minnesota. How true a general picture of Native American civilization by the shores of Gitche Gumee he may have managed to draw I cannot say. But it is certain that the real Minnehahas, when they harvested wild rice for their Hiawathas, did not do the job on any meadow.

Wild rice, the only native North American grain, grows in the lakes and rivers of Minnesota, Upper Michigan, Wisconsin, and adjoining parts of Canada. Wild rice is an aquatic grass, appropriately labeled *Zizania aquatica* in scientific nomenclature. At least the second half of the botanical name is appropriate. *Zizania,* picked as wild rice's genus name for no reason I can fathom, comes from a Greek word for a weed, probably the darnel, that grows among wheat. The vernacular name is even more misleading, since wild rice is not some uncultivated version of domesticated rice, *Oryza*, but closer in nature to wheat. The early French explorers of its native range did not help dispel the general confusion when they dubbed it *folle avoine,* or "crazy oat."

With so much misinformation surrounding wild rice, perhaps Longfellow should be pardoned for his relatively trivial error. It is a shame, though, that he did not know about the exceedingly poetic, traditional Ojibway technique for harvesting wild rice, which would have made a splendid episode in *Hiawatha.*

Instead of striking out over dry land, the Indian women, two to a canoe, collected the rice while entirely waterborne. An observer, writing in 1820, described harvesting on Big Sandy Lake:

> It is now gathered by two of the women passing around in a canoe, one sitting in the stern and pushing it along, while the other, with two small pointed sticks about three feet long, collects it in by running one of the sticks into the rice, and bending it into the canoe, while with the other she threshes out the grain. This she does on both sides of the canoe alternately, and while it is moving.

On a good day the women went home with a canoe full of grain. And that is still the way wild, so-called lake rice is harvested in Minnesota. State law regulates every aspect of the rice harvest, setting an opening day for the season, protecting Indian rights over waters on their reservations, and forbidding the use of any harvesting tools other than Indian-style sticks. Such rules were intended not only to perpetuate a charming technique but, principally, to safeguard the interests of Indians and individuals against competition from an extremely efficient harvesting machine perfected in 1923 and then quickly outlawed after a public outcry went up against it.

As a result, the rice harvest on Minnesota lakes, which normally begins in late August, is what you might call a grass-roots phenomenon involving all manner of folk—Indians and white hobbyists alike. The total crop of lake rice is not immense, averaging about 500,000 pounds a year in the seventies. But the local, atomized nature of the harvest lends it an appealing, communal quality. On the other hand, the scarcity of the grain and its prestige among gourmets have made wild rice an expensive item outside the state, one that is too valuable for many poor Indians to keep for their own use. That, at any rate, is what some Native American radicals charge, yearning perhaps for the return of precolonial days when wild rice played a crucial role in the survival of the 50,000 Ojibways who lived in the forests of the Upper Great Lakes.

Even today it is still possible to ob-

serve Ojibways processing wild rice in the unbelievably laborious traditional manner. First, the green rice has to be cured so that it will not spoil in storage and so that the hull can be removed. Originally, this was done with the heat of the sun or over smoky fires. But when white settlers introduced metal pots, Ojibways quickly switched over to them, toasting the rice in caldrons set over wood fires and stirring the grains with a canoe paddle. At this point, men take over the process. They dig a shallow hole in the ground, line it with skin, and pour in cured rice. Wearing moccasins and leather gaiters to keep rice from working its way inside the moccasins, they literally dance on the rice to loosen the hulls. To gain more leverage and better balance while they "jig," they steady themselves by holding on to poles placed outside the hole. Finally, the winnowed rice is poured over a blanket, so that the wind can blow away the chaff as the heavier grains fall to earth.

Few Indians do this any more. Commercial processors with mechanical parchers, threshers, and winnowers can do the job much faster. But the old ways have not completely died. At Cass Lake, Minnesota, I was able to purchase a small quantity of jigged rice so meticulously produced that it lacked all but the faintest light-brown trace of hull.

The majority of Ojibways prefer to sell their rice as a cash crop to commercial processors. The ultimate product is hard to fault and would probably have been approved by the Ojibways of yesteryear. At Northern Lakes Wild Rice Company in Cass Lake, for example, Ernie and Cindy Anderson do custom processing on a small scale. They live in the midst of Indians, and in the title of the cookbook they have published, *Minnesota Mahnomen Recipes,* they show their respect for Indian ways by perpetuating the Ojibway word for wild rice (*mahnomen* is also the source of the name of a neighboring tribe, the Menominees).

Strictly speaking, one could argue that the Andersons are paying lip service to a tradition they are also exploiting for personal profit. But it is hard to work up much animus against their cottage industry after you have visited the holdings of a new company that has as its aim the cultivation of *Zizania aquatica* on hundreds of acres of paddies.

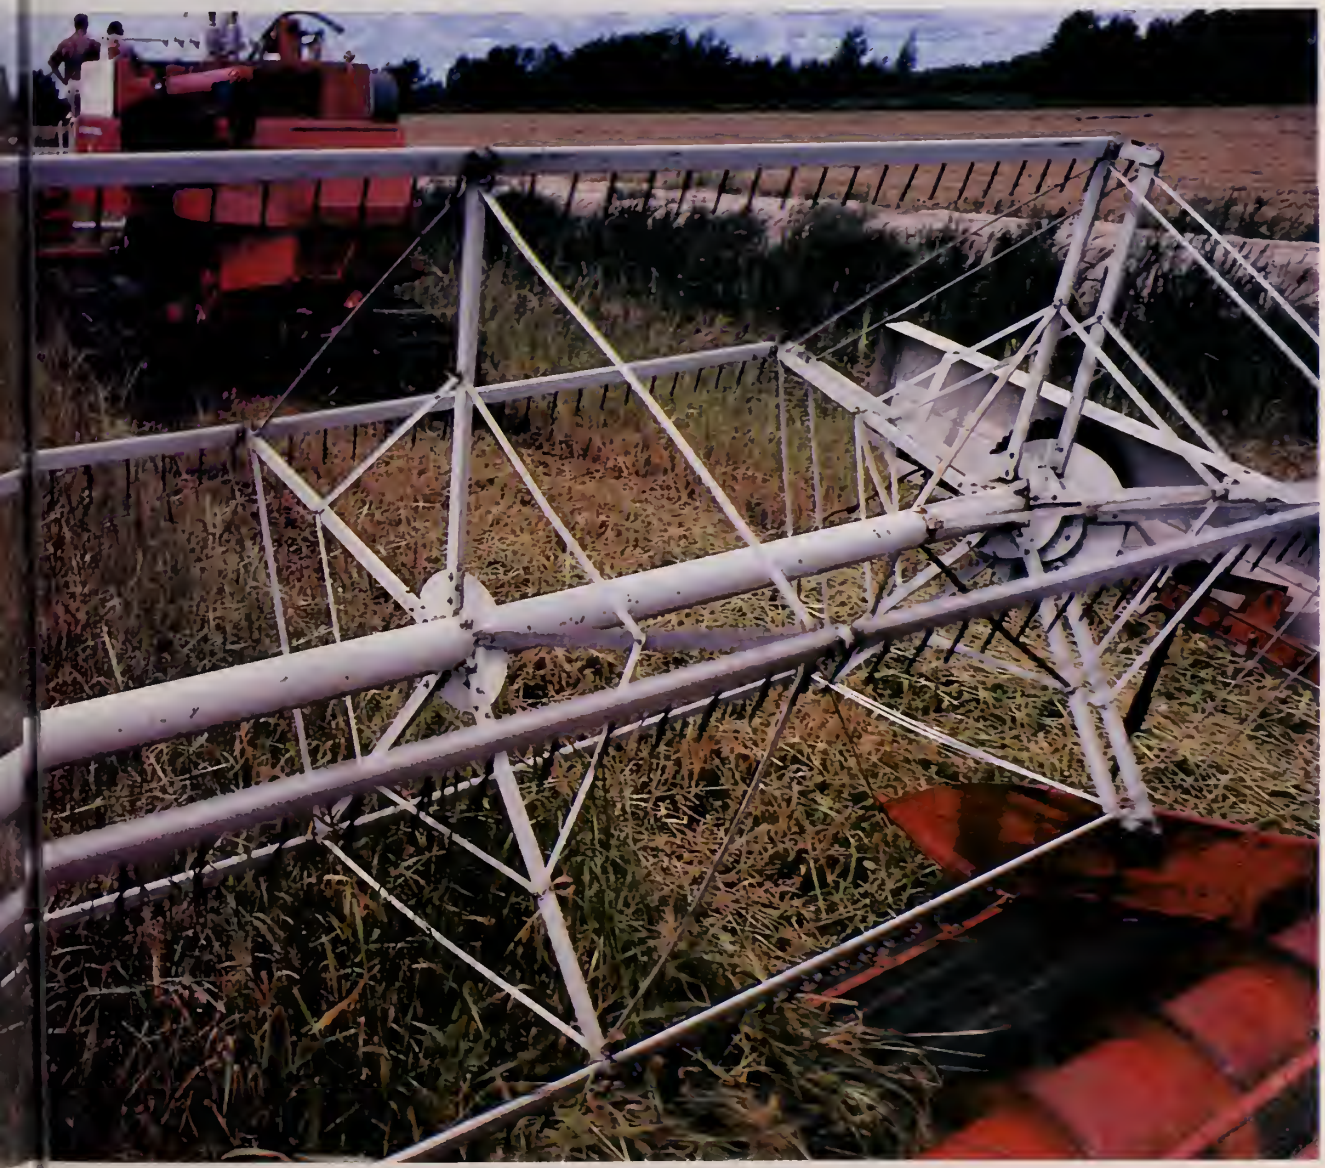
The very idea of domesticating America's most folkloric wild plant may strike you as an abomination, a final blow struck against the aboriginal order by the same kinds of free-wheeling entrepreneurs who raped the country's forests and pillaged Appalachia's hills. But I was reserving judgment as I flew over the neat paddies in the amphibious plane of one of the company's investors. After all, the original stands of wild rice on the lakes are as safe as a strict environmental code can make them. Meanwhile, below me, an agronomic drama of the first order was in full swing.

It was as if I was on hand for the domestication of corn and wheat from their original wild grasses in prehistoric times. But in twentieth-century Minnesota, a band of green-thumbed businessmen and inventive farmers are accomplishing in a decade the same job that occupied ancient agriculturists for generations.

Modern science and machinery help a great deal. Laser-guided land planes can smooth a paddy on a slight slope so that water drains in and out of an ingenious system of dikes and ditches. Old-time American ingenuity has improvised flotation wheels for a Rotavator that tills the paddies' peat soil without churning it excessively as a plow would. Combines to harvest ordinary rice, built on halftracks and full tracks suitable for soft peat, have been rigged with extra-large headers

Paddy grown wild rice is harvested by combines rigged with extra-large headers to match the plants' height.

that match the height of the wild rice plants.



These mechanized marvels were the easy part. They just cost money, lots of money. The hard part was, and to a certain extent still is, finding a strain of *Zizania aquatica* that can be sown and reaped like any other cultivated grain. Over the years many Minnesotans tried to tame wild rice, but they all failed. The plant's basic biology foiled them because the mature seeds—the part we harvest and eat—shatter at maturity and fall off the stem. Worse, seeds of the same plant mature at different times, starting with the topmost and progressing downward along a spikelike cluster. For this reason, traditional lake harvesting has to be done in several stages, with canoes passing through the same stand at intervals of several days, until all the seeds have matured and been knocked off their stems.

The paddy rice farmers can only harvest once, since the combine chews off the plants' entire spikes in one pass. For paddy production, then, the ideal wild rice plant would have seeds that did not shatter; that remained on the plant until the whole spike was ripe.

Pioneers in the paddy business like Harold Kosbau scoured lake crops looking for naturally occurring, nonshattering strains. Eventually, they found them, planted them in paddies, and by 1972, they were in business. Last year paddy production had expanded to 2.2 million pounds, roughly 80 percent of Minnesota's overall crop. And in that same period, after a sophisticated marketing effort by the paddy growers and by wild rice retailers, United States consumption tripled. Meanwhile, the retail price, especially outside Minnesota, zoomed to a level at least as high as $17 a pound. The wild rice market is wilder than the plant. Mail-order sources charge widely divergent amounts, ranging from a low of $5 per pound to $14.50 for ten ounces.

To be sure, there are different grades of wild rice, from fancy long grain to broken debris, but these are unofficial ratings, rarely mentioned and affecting price only erratically. Questions of price apart, in the new, two-tiered wild rice market, there is the further question, the most fundamental of all, Is paddy rice as good as lake rice?

Naturally, the paddy growers' stock response is, "They're genetically the same. There's no difference." This

claim is obviously false. By definition, a nonshattering strain of rice is a genetically different variety from the majority of naturally occurring plants. And the state of Minnesota is full of diehards like Ron Libertus, an Ojibway art historian and special services director for the Minnesota Department of Natural Resources, who will tell you that paddy rice is "a different product," cured longer to soften the harder seed, darker in color, ultimately quite different in taste. Paddy people deny this.

To test the claims of both sides, I collected six samples of lake and paddy rice. All the paddy rice had been industrially processed, except for one package parched and jigged in an exhibition of Indian techniques. The lake rice came from three different sources; one sample had been prepared by hand (foot?). I cooked them all until they began to split so that they would be chewy or what Italians would call *al dente*. Not all the rice turned out this way.

At one extreme, the jigged paddy rice turned to mush in minutes without passing through an intermediate, chewy stage that I could detect. At the other extreme, the very light and delicate, Indian home-processed rice was so light, subtle, and fluffy that it approached true rice in appearance and flavor. Frankly, I preferred the four intermediate varieties, which all had the gutsier, chewier, smokier conventional taste of wild rice, whether they came from lakes or paddies. No doubt, the lake varieties had a gentler feel on the tongue, a higher color, and perhaps a greater complexity of taste. But the distinction seemed to me a very thin one. From lakes or paddies all four samples tasted very good with roast duck.

Ultimately, as paddy cultivation improves its genetic base and expands still further, it may reduce lake harvesting to the status of a colorful hobby. At the moment, however, illogical prices notwithstanding, the market is absorbing lake and paddy production almost indiscriminately. Nevertheless, the advent of paddy rice has already had one clear result. More than a century too late, Longfellow has been vindicated. Minnesotans are finally harvesting wild rice on dry land.

Raymond Sokolov is a free-lance writer whose special interest is the history and preparation of food.

Basic Preparation of Wild Rice

1 cup wild rice
Salt

1. Put rice and 1 teaspoon salt in a saucepan with 3 cups water.
2. Bring to a boil, lower heat, and simmer, covered, for about 30 minutes. It is impossible to give a precise cooking time. Some small-grained, highly polished varieties will cook quickly. Others will take longer, up to 50 minutes. But wild rice is not nearly so sensitive as ordinary rice. By all means uncover the pan and taste as often as you like. If cooked too long, wild rice turns to mush and loses much of its taste and nutritional value. But if you catch it just as the grains begin to split, it will have an appealingly crunchy texture and a nutty flavor.
3. Drain and serve. Leftover rice will keep for several days under refrigeration. Or it can be frozen. It will also stand up to reheating very nicely, especially if it has not been overcooked the first time around.

Yield: About 4 cups or 6 servings

Wild Rice Muffins

(Adapted from *Wild Rice For All Seasons Cookbook*, by Beth Anderson. $6.95 postpaid from Minnehaha Publishing, Suite 406, 625 Second Avenue, Minneapolis, Minnesota 55402)

1 cup cooked wild rice
2 eggs, lightly beaten
5 tablespoons oil
1 cup milk
1¼ cups flour
1 tablespoon baking powder
½ teaspoon salt
3 tablespoons sugar

1. Preheat oven to 425 degrees. Grease a 12-muffin tin.
2. Stir the wild rice together with the eggs, oil, and milk in a mixing bowl.
3. Combine the flour, baking powder, salt, and sugar in another bowl. Stir together until well mixed.
4. Stir the dry ingredients into the liquid ingredients, gradually and thoroughly, until blended.
5. Spoon the batter into the muffin cups. Bake 15 to 18 minutes, until lightly browned.

Yield: 1 dozen muffins

Real quality has a way of creating its own image.

Images can be fleeting. A shadow. A rippling picture in a pond. Or they can be as lasting as a lifetime. A lifetime of hard work.

As a maker of home appliances, Whirlpool Corporation believes that a lasting quality image is simply the reflection of the people who build and stand behind the product. Special people. Motivated by pride of concept. Of craftsmanship. Of their ability to make things that last.

This is why we take pride in stocking parts for as many years as we do. Why we maintain a toll-free Cool-Line® service number* you can call 24 hours a day. And why we have a nationwide organization of authorized Tech-Care® service companies that are as close to you as your phone book.

You see, at Whirlpool we believe every appliance we build should create its own image of quality. And do it for one person—you.

It's our way of saying this is more than just an appliance. This is our way of life.

BAILEYS.
THE ORIGINAL IRISH CREAM LIQUEUR.

THE CREAM IS REAL. THE WHISKEY IS REAL.
ONLY THE TASTE IS MAGIC!

My inclination toward anthropology probably began in my childhood," says **Gertrude Enders Huntington.** "When I was ten years old I visited the Cuna Indians off the coast of Panama. I was the first white female child most of the women had ever seen." Huntington attended Oberlin College, graduated from Swarthmore College, and received her Ph.D. from Yale University. She has taught biology, done fieldwork in Turkey, and written a five-volume dissertation entitled *Dove at the Window: A Study of an Old Order Amish Community in Ohio.* As principal fieldworker on the Hutterite Socialization Study, she and her family lived as Hutterites in a Canadian colony for an extended period of time.

As a game biologist for the Alaska Department of Fish and Game, **Dan Strickland** monitored the walrus harvest off the islands of Saint Lawrence and Little Diomede. These experiences drew him into the thick of the controversy involving walrus hunting and Eskimo subsistence. Currently working as a commercial fisherman in the Alaskan gill net salmon industry, Strickland is also doing research on the Prince William Sound fishery. When not fishing or watching walrus, he backpacks and skis cross-country in the Alaskan bush.

George A. Hendrey is deeply concerned with the fate of fish and other life forms in freshwater lakes and streams, although he admits he doesn't have the patience to be a fisherman himself. Trained in aquatic biology, he has done limnological research in the United States and Norway. Born and raised in Seattle, Hendrey likes to spend time in the mountains and has arranged his professional life "so as to make that possible." His favorite sport used to be downhill skiing, but during a three-year stay in Norway, he became a convert to the cross-country variety. Hendrey earned his B.A. and Ph.D. degrees at the University of Washington. Since 1977 he has served as an ecologist in the Department of Energy and Environment at Brookhaven National Laboratory in Upton, Long Island.

When he was fifteen, German-born **Erik Zimen** joined his family for a one-year visit to the United States. During their stay, the Berliners viewed the exhibitions at the American Museum of Natural History. Zimen, a research assistant at the University of Saarbrücken, West Germany, writes that his interest in ethology began at that time. After receiving his Ph.D. in zoology, physiology, and anthropology from the University of Kiel, he conducted fieldwork on wolf ecology and conservation in the Abruzzi Mountains of Italy. He has also done work on the ecology of the red fox in southwestern Germany and is planning an evaluation of the status of the wolf in Poland, Czechoslovakia, Romania, and Yugoslavia.

THE COMPUTER ALSO HEATS THE BUILDING.

The energy crunch.

It's been on our minds at IBM for quite some time.

Back in 1973 we began offering computer systems that manage energy as only a computer system can.

These systems take thousands of energy-saving actions every day, based on information about weather conditions, use patterns, and other factors.

They turn lights on and off. Turn heat and air conditioning units on and off. Control hot water heaters as needed. And more. All to prevent waste.

In one of our customer's buildings, a system we installed cut the power bill by over $8000 in the first month.

And in the headquarters building of the IBM division that builds these systems, energy management equipment recycles heat generated by the computer installation itself. The outside temperature has to drop below 11° F before the boilers need to be turned on.

Energy management systems obviously conserve energy.

But what they really do is manage things better and more economically than people can manage them alone.

That's what computer systems are very, very good at doing. IBM

Culinary Themes and Variations

Traditional seasoning practices provide both a sense of familiarity and a source of variety

by Elisabeth Rozin and Paul Rozin

Every morning in a small village in the southern highlands of Mexico one can hear in every home the rhythmic sounds of the grinding stone. Between these stones, or *metates,* are, without fail, chili peppers, and frequently tomatoes, being ground into the *salsa* ("sauce") for the day. The *salsa* will appear at almost every meal; when it is absent, the chili peppers, often combined with tomato or lime, turn up as components of cooked solid foods and soups. A ubiquitous feature of Mexican cuisine, the chili pepper, along with the staples corn and beans, is an essential part of what makes Mexican food "Mexican."

This Mexican village is not unique, for the same processes take place in every other Mexican village although the ingredients may vary slightly from one village to another. So it is in other parts of the world as well. One can observe in the Brahman Tamil cuisine of southern India, for example, the same kind of daily seasoning preparation: the soaking of tamarind, the grinding of chili pepper, the frying of mustard seed, turmeric, and hing powder (asafetida). These and other flavorings, used daily on almost all cooked staple foods, create the identity of this cuisine.

Such flavoring practices are very widespread but seem to occur most frequently in tropical or semitropical areas or, what may be the same thing, in cultures that depend more heavily on plant foods than animal foods. Thus the most distinctive and easily described seasoning traditions occur in China, Southeast Asia, Africa, India, the Mediterranean, and South and Central America. Seasoning practices may range from the use of one specific, pervasive flavoring ingredient (the use of coconut in the islands of Oceania) to much more complex and elaborate bonds or combinations of flavoring ingredients (the spice mixtures of North African or Indian cuisine). Within cultures that characteristically season their foods, the use of combinations of flavoring ingredients is the most common technique: the soy sauce and rice wine and ginger root bond of China; the soy sauce and sesame seed and chili bond of Korea; the "curry" spice mixtures of India; the tomato and garlic and olive oil bond of southern Italy. These distinctive and pervasive flavoring combinations, which we call "flavor principles," seem to impart a clear and characteristic identity to the foods of any group. Cultures that reliably season their cooked foods do not, for the most part, utilize these seasonings in sweets and beverages.

The use of characteristic seasonings, whether singly or in combination, is not universal in human culinary practice; in cuisines that have a high proportion of animal foods (meat or dairy products) in their diet and in many cuisines of temperate and polar regions there is typically no strong dependence on flavoring ingredients. This tendency results in culinary products that are relatively less "marked" than the products of cuisines that season heavily. Characteristic seasonings provide a gustatory "theme" that identifies and unites the products of a cuisine so that, for example, having sampled at random several Mexican or Indian dishes, one would have a good chance of identifying new instances of dishes from these cuisines. This would probably not be the case in the relatively less marked cuisines of England or Germany.

Most of the world's people seem to belong to well-marked cuisine groups that create culinary products with distinctive and describable gustatory themes. The traditional seasonings are "loved" by the members of these groups. They find it difficult to imagine food prepared without them. Faced with a hypothetical absence of chili, for instance, members of a Mexican village kept inventing ways of getting some—from neighbors, stores, or markets—rather than face the possibility of eating a meal without it. Chili is craved: food simply doesn't taste good without it.

This attachment to traditional flavorings seems to be as strong, if not stronger, than the attachment to traditional staple foods. Human beings are remarkably conservative in their food habits and are typically reluctant to try new foods and to abandon old familiar ones. Although some new foods have been introduced and accepted in both Mexico and China, for example, the ancient flavoring traditions, many of them thousands of years old, persist unchanged to this day. Traditional flavorings are high-priority culinary items and immigrant groups typically go to great lengths and expense to procure them in foreign settings. After many generations in the mixed culture of Israel, the basic flavorings of the original home country (either Eastern European or Mediterranean or indigenous Israeli) still predominate in the individual's daily diet.

The desire to re-create familiar tastes is illustrated nowhere more poignantly than in the behavior of Vietnamese refugees in an American resettlement camp that we visited in the fall of 1975. Vietnamese food is characteristically seasoned with *nuoc*

1981 FORD BRONCO: MILES AHEAD IN MPG AND ADVANCED DESIGN.

Bronco, the 4-wheel utility economy champ. It's the family 4-wheeler totally redesigned last year for the needs of the 80's. The only one that can give you advanced features like tough, independent front suspension and optional 4-speed overdrive transmission to boost fuel economy, particularly at highway speeds. Any way you figure, you're ahead in a tough Bronco!

FORD DIVISION Ford

mam, a salty, fermented fish sauce, typically mixed with vinegar and chili. The camp kitchens, staffed by U.S. Army cooks, attempted to accommodate Vietnamese taste by providing some traditional staple foods: chicken, fish, rice, vegetables. But the well-loved *nuoc mam* was not available. When the kitchen staff discovered, by trial and error, that the most popular flavorings were soy sauce and hot pepper sauce, a bottle of each was always placed on every table in the mess hall. The cooks told us, with some incredulity, that the refugees would pour soy sauce and hot pepper sauce on all their foods, mix them together, and then eat them. They went through supplies of these sauces at a most remarkable rate. The refugees were doing the best they could, in a strange environment and with limited ingredients, to duplicate the traditional flavors of their cuisine. (*Nuoc mam* is now widely available in Oriental groceries throughout the United States; the demands of the Vietnamese have produced a steady supply.)

The flavoring of food—that is, the deliberate manipulation of food by adding ingredients that will reliably alter the taste—is a uniquely human behavior. There are no animals that characteristically mix their foods with anything that could be called a flavoring, even including the possibility of marking the food with a bodily secretion. The one possible exception is the troupe of monkeys on Koshima Island in Japan that has developed a tradition, "invented" by an adult female, of dipping sweet potatoes in saltwater before eating them. This one example may be the only reported seasoning behavior from the animal kingdom.

Why do human beings, or at least most human beings, flavor their foods? What is the function of seasoning traditions, handed down from one generation to the next? One can understand how the attachment to the flavors of their native cuisine might develop in individuals as a result of continued exposure from early childhood (and possibly even earlier still from mother's milk). But what is the adaptive value of this generally widespread and ancient practice?

Surely, any particular flavoring ingredients used—chili, cumin, garlic, or whatever—are largely determined by their availability in the environment. But availability alone cannot explain the exclusive, persistent, and prevalent use of certain flavorings in any culture. Frequently, some available flavorings are rejected, while others not easily obtained are widely sought after. The age of exploration in Europe, for example, was largely motivated by a specific lust for seasoning ingredients, particularly pepper.

It is possible that some flavoring ingredients have specific biological value, in terms of either nutritive or physiological effects. Because such seasoning elements are typically eaten in small amounts, they cannot supply a significant amount of macronutrients, like protein and fat, but they might well provide valuable vitamins or minerals. Chili pepper, for example, is a very rich source of vitamins A and C. These vitamins are in short supply in the diets of some cultures that use chili; in these cases chili can provide a significant percentage of vitamin A and C requirements, for example, in some areas of Mexico.

A few flavoring ingredients may have medicinal benefits: one of the better documented examples is the antibacterial effect of garlic. Certain physiological effects of the ingestion of some flavoring ingredients may also have adaptive value: chili pepper causes facial sweating, thereby facilitating heat loss in hot environments. Like some other irritant spices, chili stimulates salivation, gastric secretion, and gut motility, and thus may facilitate the chewing and digestion of high-starch diets. Research and ingenuity could probably provide a possible specific effect for each of the many flavoring ingredients used throughout the world. Although such adaptive explanations might well be valid, they are unsatisfactory because they provide a set of individual and specific explanations for a class of related and general phenomena. And such specific explanations cannot account for the pervasive use of seasonings on almost all staple foods.

There are several other possible general explanations. Traditional flavors may serve the same function as traditional costume or traditional religious practice. They are a means of defining a culture group, of identifying an individual with it, and of separating that group from others. Whatever broad human needs are served by such visible in-group behavior, distinctive culinary practices must surely be a part of it.

Another explanation focuses on the salient sensory properties of flavoring ingredients. These elements, particularly when combined in the bonds of flavor principles, almost always have a strong and distinctive flavor. From a broad cultural-ecological perspective, it is those cultures that rely on a bland starch staple with small amounts of meat that have the most marked cuisines in terms of flavor. Indeed, the common explanation offered by individuals from a marked cuisine that the flavors add "zest" or "taste" to their food has some force.

Flavoring ingredients may also be distinctively colored—for example, chili, turmeric, saffron, soy sauce—and may thus impart a characteristic rich and warm color to the food. Again, with bland or light-colored staples (rice, refined wheat), color can provide visual zest, and through both taste and appearance give a meaty quality to the diet. Given that meat is a highly preferred food in almost all cultures, flavoring traditions might well be a response to an absence or shortage of meat in the diet.

A final explanation, which we shall develop more fully, ascribes the widespread use of flavor principles to a basic feature of human biology: our omnivorous heritage.

Human beings are omnivores, or food "generalists," that is, they consume a wide variety of food substances. Unlike food "specialists," who rely almost completely on one or a few varieties of food, omnivores can select their diet from a theoretically almost limitless range of items, a range defined by availability in the environment and by competition with other species. (For convenience, we will use the term omnivore but our comments hold for all generalists, including general herbivores.) The omnivore has much greater flexibility in exploiting the potential nutrient sources of the environment and in exploring and invading new habitats. Furthermore, by consuming a wide variety of foods, the omnivore can minimize the effects of mildly toxic or nutritionally imbalanced substances by utilizing them as only partial nutritional support.

A major cost of omnivorousness is that it makes great demands on behavioral capacities. The food specialist consumes such a small variety of foods that recognition of appropriate food items (specific types of leaves, flying insects, and so on) can be genetically built in. Specifically tuned receptors could never be constructed for the

Please enter my trial subscription to this completely new Color Slide Program and send me the Picasso Album (including 20 color slides and 47-page illustrated lecture). Bill me only $1, plus a few cents tax and shipping. If I am not delighted with this introductory package, I may return everything within 15 days, cancel my subscription, and owe nothing.

If I do continue, you will send me a new Color Slide Album approximately every six weeks (for 15 days trial examination) and bill me at the subscriber's low price $12.95, plus tax and shipping. I may take as few or as many Albums as I like, and may stop whenever I wish. After my fourth shipment I will be given a choice of receiving all remaining Albums in one convenient shipment, or continuing with single album shipments.

☐ Check here if you wish the Kodak Carousel BC 604 Projector, and remit the low subscriber's price of only $99.50 plus tax, with this card in envelope addressed to McGraw-Hill Color Slide Program of the Great Masters. If not delighted, return projector within 15 days for full refund.

This offer applies to U.S. only.

Included—at no extra cost—this Illustrated 47-page Gallery Lecture Guide

20 Color Slides of PICASSO Masterpieces for only $1 (comparable value $20)

THREE MUSICIANS (1921)—a monumental work of Picasso's late Cubist style.

ACROBAT'S FAMILY WITH AN APE (1905)—a "Rose Period" masterpiece, is notable for its span of contrasting forms.

WOMAN'S PROFILE ON RED BACKGROUND (1959) a beautiful example of Picasso's late style.

THE BLIND MAN'S MEAL (1903)—This haunting work from Picasso's "Blue Period" reflects his obsessive fear of blindness.

Turn your living room into your own private Art Gallery

Includes this Illustrated 47-page Gallery Lecture Guide

HERE'S WHAT YOU GET FOR ONLY $1

PABLO PICASSO, a handsome Album with 20 beautiful color slides, including the playful and amusing "Three Musicians," the memorable portrait, "Gertrude Stein" . . . "The Women of Algiers" . . . "Mandolin and Guitar" . . . and other dazzling Picasso masterpieces. The Album also contains an illustrated 47-page guided lecture by modern-art expert John Galloway, who gives you revealing background on the paintings and the prolific genius who created them.

The Color Slide Program of the Great Masters

You're invited to a feast.

Come enjoy a glorious banquet of form, color, visual rhythm, and inexhaustible imagination . . . created by the towering genius of 20th century art—Picasso!

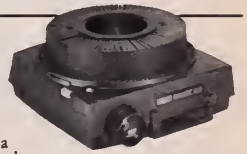
No other artist ever produced so many masterpieces that appear so unlike each other — or mastered so many styles, only to move beyond them. As William S. Rubin of New York's Museum of Modern Art has observed: "More than just a great artist, Picasso was a phenomenon. There is virtually nothing in modern art that he has not invented, influenced, or practiced."

PABLO PICASSO—the complete Art Album with 20 full-color slides and handsomely illustrated Gallery Lecture Guide—is yours for only $1.00 as your introduction to the McGraw-Hill Color Slide Program of the Great Masters. There is no obligation to buy anything more.

View the priceless works of art in the full glory of the originals

Each lavish Album contains twenty color slides devoted to the works of a famous master. Created by art photography specialists in Florence, Italy, these exquisite 35mm slides achieve what small print and art reproductions cannot — for they capture the authentic colors of the original works . . . with every subtle line and detail brilliantly revealed. And they permit you to view each priceless painting on your home screen in the full glory of the original.

In addition, bound into each Album is an illustrated, 47-page Guide in which a noted authority points out important aspects of each painting and shares with you fascinating glimpses of the artist himself.



As you view the paintings projected on your wall and read the absorbing commentary, you and your family will discover a whole new dimension in the enjoyment of art. Indeed, it is much like taking your own "private tour" with an art expert at your side.

The Program is flexible — the cost is low. Approximately every six weeks, you are offered a complete new Color Slide Album of 20 distinctive slides and an illustrated lecture. Forthcoming Albums will be devoted to the lives and works of such great masters as Michelangelo, Winslow Homer, Rembrandt, Gauguin, and Da Vinci, Chagall, Van Gogh, Lautrec, etc.

If the slides were available from museums, you would expect to pay as much as $20 a set. Yet, as a member of this new Program, you pay only $12.95 for each complete Album—including 20 color slides and 47-page illustrated lecture. And you may take just as many as you like.

Accept this $1 demonstration offer

To introduce you to the McGraw-Hill Color Slide Program of the Great Masters, we will send you PICASSO, complete for 15 days trial. If you are delighted with the demonstration, send only $1, plus a few cents for tax and shipping. If not thrilled with the introductory Album, simply return it within 15 days; and you will be under no further obligation. Mail the attached card today.

If you do not have a projector: here's an unusual opportunity. We can offer you the sensational Kodak Carousel BC 604 Projector supplied with a 300 watt lamp, and 4-inch f/2.8 Ektanar lens. This top-rated projector shows all the regular 2" x 2" 35mm slides up to 1/16-inch thick. It has dependable gravity feed and you have instant access to any one of its 140-slide capacity at any time. List price $139.50—subscribers' low price only $99.50 plus tax (you SAVE $40). Send remittance with trial subscription form. If not completely delighted with the projector, return it in 15 days for full refund.

If Reply Card has been removed, write McGraw-Hill Color Slide Program of the Great Masters. Dept. AY-149, 1221 Ave. of the Americas, N.Y., N.Y. 10020.

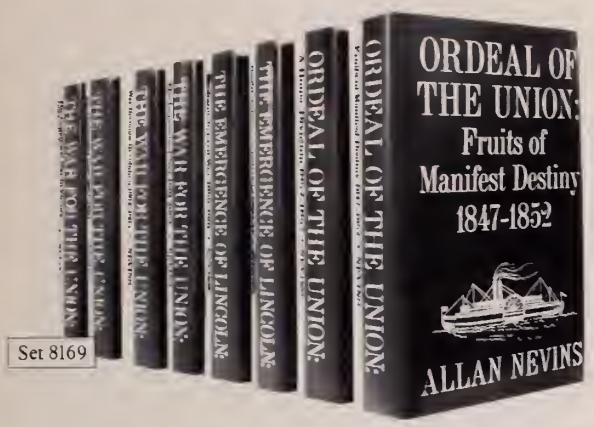
huge number of nutritive or dangerous substances that the omnivore encounters. The omnivore must have another type of system for identifying and evaluating these many substances; this is especially important because of the high incidence of toxic substances in the natural world.

Without an innate food recognition system, how does the generalist manage? Although some mammalian omnivores, including humans, do have minimal preprogrammed guidelines (approach to sweet tastes and avoidance of bitter tastes), individual experience predominates in the evaluation of foods. And of course humans have the mediation of culture, which includes accumulated knowledge about valuable and dangerous substances and methods for treating certain items that, once detoxified, are nutritionally beneficial.

Of all behavior, eating is surely the most intimate because it involves the irrevocable incorporation of things into the body; once past the lips and down the gullet the substance becomes at least cognitively a part of the organism. Such an interaction must be both intensely satisfying and extremely threatening. Strong, positive, affective responses accompany eating, while, when new foods are involved, the possibility of bodily harm promotes fear and hesitation. This approach–avoidance conflict is one aspect of the omnivore's dilemma. Trying new foods is at the core of omnivorousness, but so is being wary of them. A delayed, cautious, and gingerly sampling of new foods is common in a number of omnivorous species.

Within the familiarity of one's culture the fear side of eating is attenuated. But when one leaves the safety of the home environment and travels to far and exotic places, the conflict appears: there is an interest in new foods and a simultaneous fear of eating them, a conflict frequently resolved by restricting eating to the safe haven of the Cairo Hilton or a MacDonald's in Bangkok. (Indeed, the uniformity and total predictability of the fast-food chains may be a response to this side of the omnivore's dilemma.) A person may both seek and withdraw from exotic foods, and the balance may shift in different individuals and in different circumstances. Although the preference for a new food increases the more times it is experienced without negative consequences, this may be, at least partially, a result of the dissipation of fear of new things. However, extensive exposure may also lead to boredom and rejection. This encourages the omnivore to continue exploring new food sources and discourages heavy reliance on one food. And so we have a second aspect of the omnivore's dilemma, which can now be seen as twofold: (1) curiosity about new foods versus fear of new foods and (2) the satisfaction with familiar food versus the boredom that overexposure can produce.

It is our belief that the widespread human tendency to season foods with recurrent, predictable combinations of flavoring ingredients can be seen as a cultural response to the omnivore's dilemma. The ambivalence of eating, the pleasure–fear balance, depends on the familiarity of the food. Reliably clothing the food in a distinctive and familiar flavor can tip the balance to the side of pleasure: it provides a taste that has always been safe and enjoyable, that is associated with satiety and the appropriate social context. The flavor furnishes a familiar frame for the food of a culture, passed along from generation to generation.



If the approach–avoidance conflict can be significantly reduced by the use of familiar, traditional flavors, it might well be an adaptive means of disseminating a nutritious, new food staple within a culture. By labeling a food with the appropriate flavor, it is "certified," as it were, as familiar and safe to eat. Having discovered the safety and nutritional value of a new food through personal experience or through information received from outside, the pioneer "sampler" within a culture could announce its acceptability by treating it as a traditional food, preparing it with familiar flavor principles and cooking techniques. Indeed, Parmentier, the eighteenth-century French agriculturist, did just this in order to persuade the French people to accept the potato, a valuable food staple brought from the New World. The French would have nothing to do with this new food until Parmentier showed them how to prepare it in traditional ways and with familiar seasonings: butter, cheese, herbs. The strategy worked, and the potato has risen in the French culinary repertoire from initial rejection to enormous popularity.

We don't know very much about how, on the individual level, new foods

are introduced into a culture. We do have some data, however, indicating the importance of flavor principles in treating new food items. In a Mexican village where we observed food habits closely, a number of women were asked how they would prepare three items they had never eaten before. The three "foods" were sardines (one of the few canned foods available in the village store but rejected by a majority of the residents), alfalfa (an animal food), and a common shrub not considered food. All responses included flavoring the item with chili, the indispensable flavor-principle component. Several of the other responses indicated the use of lime, another traditional flavoring ingredient. In all these cases, the women had no reason to believe these new foods would cause them any harm, although they had no desire to try them. When faced with hypothetical use, however, they treated them like familiar foods. There is something to be said then for the reassuring nature of traditional seasonings; they are the familiar culinary theme, linking together the known and the traditional with the new and the unfamiliar.

But what of the omnivore's second problem, the need for variety and the reduction of boredom? With the rise of agriculture and the growing dependence on a few staple crops, the number of different foods eaten by most cultures dropped; it is probably still the hunter-gatherer who, even in marginal environments, consumes the greatest variety of food items. Elaborate culinary preparation (in terms of techniques, equipment, and novel combinations of ingredients) can produce variety, and this greater complexity of culinary procedure occurs in virtually all cultures that rely primarily on the staple-plant diet. But how can the placing of a recurrent flavor combination on almost all foods at almost all meals, reassuring as it may be, also provide variety and reduce boredom?

The answer may come from a close study of the use of flavor principles in cuisine. What seems a monotonous repetition of flavorings may well be an illusion of the outsider, just as all red burgundies taste alike to the inexperienced wine drinker. A closer look at actual culinary practice reveals a rich and subtle variation of flavoring from dish to dish and from meal to meal. In the Mexican village we studied, for example, chili pepper is used in many ways. It is cooked into soups and stews or sliced and placed upon other foods or ground into a sauce, often with tomatoes and other ingredients. At least ten types of chili peppers are used in this village: some are fresh, some are dried, some are red, others green, some strongly piquant, others less so. They differ somewhat in the type of "burn" they produce in the mouth. And villagers assure us that each type of chili has a different taste. Some kinds of peppers are used interchangeably with others in the making of soups or sauce. A few may be mixed together one day, a different combination on the next, but their use is far from random: some varieties are specified for certain culinary preparations. The chili ancho, for example, a large and relatively mild variety, is used almost exclusively in *moles*, the traditional stewed meat dish of the region. The number of different kinds of chili peppers available in the area is quite large. Nine homes that we surveyed had from three to six different chilis in the house, while in the large regional market of Oaxaca, dozens of varieties can be found. Within the single "theme" of this Mexican chili pepper flavor principle there is a great deal of subtle and controlled variation.

The same kind of theme and variation can be shown to function in other cuisines that consistently utilize recurrent combinations of flavoring ingredients. Indian cookery is characterized by a flavor that naïve outsiders call "curry"; curry, in fact, does not refer to the flavor of the food but to dishes that have a sauce. Within the realm of curried, or sauced, preparations, there is no single flavor but, again, a recurrent combination of ingredients that are manipulated with great subtlety and surprising variety. Brahman Tamil cuisine of southern India relies heavily on several core seasoning ingredients, including chili pepper, asafetida, mustard seed, tamarind, fresh coriander, and turmeric. A close inspection of Tamil recipes, however, reveals that this general theme is varied from dish to dish: sometimes all the ingredients appear, sometimes only one or two; the relative proportions differ from preparation to preparation; and the basic flavor is varied with the frequent addition of other seasoning ingredients such as coconut, coriander seed, and cumin. Again, what may look and, indeed, taste, like the very same thing to the outsider is not the same thing at all to the insider. Simple and complex variations are created by the individual cook within the thematic limits set by the traditions of the cuisine.

We suggest, then, that the prevalent human practice of adding characteristic combinations of flavors to most foods may be the result of our omnivorous heritage and an expression of our unique humanity: we have other things to do with food than merely to consume it. To appease our fear of the new and to support our satisfaction with the familiar, we create a label or theme. But at the same time, to avoid monotony and to satisfy our desire for variety, we play with the theme, fashioning as we do so, the elaborate and richly textured composition we call cuisine.

Elisabeth Rozin, author of The Flavor Principle Cookbook, *teaches and writes about cuisine and is a chef in Philadelphia. Paul Rozin, professor of psychology at the University of Pennsylvania, is a psychobiologist. His wife's interest in flavor principles drew him into the study of human food habits and how people develop likes and dislikes for foods.*

Some people feel...

"So what if I'm young. I've never had an accident or even gotten a ticket. Why should I pay the highest insurance rates?"

That's why we want you to know...

We understand how you feel. You've got a good driving record, and that's great. And you don't expect to have an accident. No one does. But the fact is that good drivers as well as bad have accidents. That's why insurance protection exists.

No one can predict which individual is going to have an accident. But we can predict the accident potential for groups of drivers who share similar characteristics. This is the only way possible to make auto insurance rates.

Insurance companies set their rates to reflect how often they have to pay claims of insured groups and how much those claims cost. This is done for each state and for each rating territory within the state.

Year after year, without exception, statistics show a consistent pattern: younger drivers have more accidents than older drivers. Young males have more accidents than young females. And young unmarried males have more accidents than young married men.

The fairest way to distribute accident costs is for each driver to pay an insurance rate that reflects as closely as possible the exposure to loss of his or her group. Of course, differences within the groups also are taken into account. Among them are the age and type of car and how the car is used (whether for business, pleasure or commuting).

But take heart. If you have a good driving record, you will pay less than others in your group who have been involved in serious accidents or who have been guilty of major traffic law violations. And, as you get older, the accident potential of your group will decline, and so will your rates.

We're working to keep insurance affordable.

This message presented by the **American Insurance Association,** 85 John Street, NY, NY 10038

Hyena Myths and Realities

Both male and female genitals are strikingly similar. Why?

by Stephen Jay Gould

I freely admit that the spotted, or laughing, hyena is not the loveliest animal to behold. Still, it scarcely deserved the poor reputation imposed upon it by our illustrious forebears. Three myths about hyenas helped to inspire the loathing commentary of ancient texts.

Hyenas, first of all, were regarded as scavengers and consumers of carrion. In his *Natural History,* Pliny the Elder (A.D. 23–79) spoke of them as the only animals that dig up graves in search of corpses (*ab uno animali sepulchra erui inquisitione corporum*). Conrad Gesner, the great sixteenth-century cataloger of natural history, reported that they gorge themselves so gluttonously after finding a corpse that their bellies swell to become taut as a drum. They then seek a narrow place between two trees or stones, force themselves through it, and extrude the remains of their meal simultaneously at both ends.

Hans Kruuk, who spent years studying spotted hyenas on their home turf (the plains of East Africa), has labored to dispel these ancient myths (see his book *The Spotted Hyena*, University of Chicago Press, 1972). He reports that hyenas will scavenge when they get the opportunity. (Almost all carnivores, including the noble lion, will happily feast upon the dead product of another animal's labor.) But spotted hyenas live in hunting clans of up to eighty animals. Each clan controls a territory and kills most of its own food —mainly zebra and wildebeest—in communal, nocturnal pursuit.

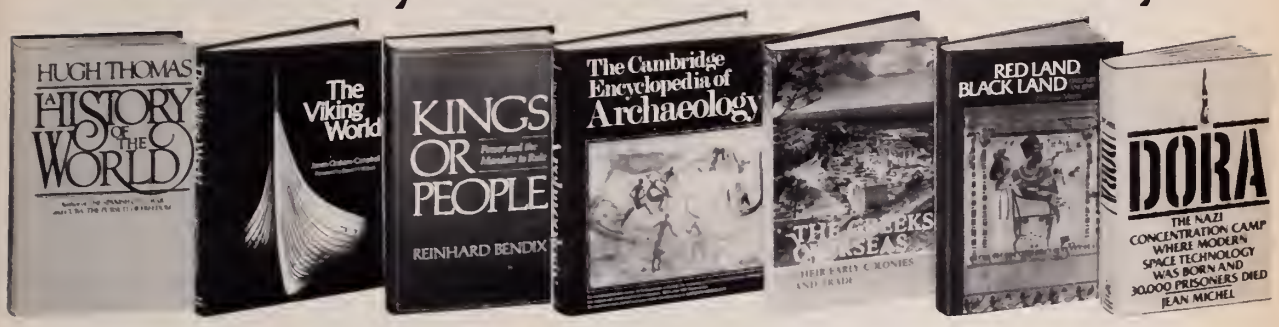
As a second insult, hyenas were widely regarded as hybrids. Sir Walter Raleigh excluded them from Noah's ark in 1614 since he believed that God had only saved the purely bred. Hyenas were reconstituted after the flood through the unnatural union of a dog and cat. In fact, the three living species of hyena form a family of their own within the order Carnivora. They are most closely related to the viverrids (weasels and their allies).

As a final, phony blot on their escutcheon, and in the unkindest cut of all, many ancient writers charged that hyenas were hermaphrodites, bearing both male and female organs. The medieval bestiaries, always trying to draw a moral lesson from the depravity of beasts, focused on this supposed sexual ambivalence. A twelfth-century document, translated by T. H. White, declared:

> Since they are neither male nor female, they are neither faithful nor pagan, but are obviously the people concerning whom Solomon said: "A man of double mind is inconstant in all his ways." About whom also the Lord said: "Thou canst not serve God and Mammon."

But hyenas also had some formidable defenders against this particular calumny. Aristotle himself had declared in the *Historia animalium:* "The statement is made that the hyena has both male and female sexual organs; but this is untrue."

Aristotle—and not for the first time —was right of course. But the legend had arisen for a good reason. Female hyenas are virtually indistinguishable from males. Their clitoris is enlarged and extended to form an organ of the same size, shape, and position as the male penis. It can also be erected. Their labia have folded up and fused to form a false scrotum that is not discernibly different in external form or location from the true scrotum of males. It even contains fatty tissue forming two swellings easily mistaken for testicles. Authors of the most recent paper on spotted hyenas found the appearance of males and females "so close that sex could only be determined with certainty by palpation of the scrotum. Testes could be located in the scrotum of the male compared with soft adipose tissue in the false scrotum of the female."



British zoologist L. Harrison Matthews wrote the most extensive anatomical description of the hyena's sexual anatomy in 1939 (*Philosophical Transactions of the Royal Society of London,* vol. 230). He described the peniform clitoris, emphasizing that it is no smaller than the male penis, is equally constricted to a single slitlike opening at the tip, and is as subject to erection as its male counterpart. He concluded his dry and precise pages of description with as forceful a statement of wonder as measured British scientific prose would allow: "It is probably one of the most unusual of the forms which the external orifice of the urogenital canal takes amongst female mammals."

Matthews also investigated the interesting question of how hyenas do it, given a female orifice no larger than the slit of a male's penis. "In the pre-pubertal state," he writes, "these functions are obviously impossible, owing to the minute size of the opening." But as the female matures the slit gradually lengthens and "creeps down round the ventral surface . . . travelling down the midline" until it forms an orifice 1.5 cm long and extending from the tip of the clitoris to its base. This lengthening of the slit and a subsequent enlargement of the nipples following pregnancy and parturition help distinguish older females from males. We can now understand the basis for ancient myths that hyenas were either simultaneous hermaphrodites (bearing male and female organs at the same time) or male for part of their life and then female.

Nature's oddities cry out for explanation, and we must ask what advantages females gain from looking like males. Immediately, we come upon the other most striking oddity of hyena biology: females not only resemble males; they are also larger than males, contrary to the usual pattern in mammals, including humans. Females in Kruuk's East African clans averaged 120 pounds in body weight versus 107 pounds for males. Moreover, they lead the clans in hunting and defense of territory and are generally dominant over males in individual contacts. Dominance is not merely a result of larger size because

37391-2. THE CELTIC WORLD. *Barry Cunliffe.* Superb archaeological-historical survey. *Counts as 2 of your 3 books.* **$39.95**

87680. A WORLD HISTORY. *William H. McNeill.* Classic narrative of the four major Old World civilizations—the Middle East, India, China, and Europe. **$19.95**

37262. CAESAR'S INVASION OF BRITAIN. *Peter Berresford Ellis.* **$17.50**

85838. VICTORIAN WORKING WOMEN: Portraits from Life. *Michael Hiley.* Social history of the working-class poor. **$17.50**

78304. SIDESHOW: Kissinger, Nixon and the Destruction of Cambodia. *William Shawcross.* **$13.95**

62915-2. MONUMENTS OF CIVILIZATION: Ancient Cambodia. *Mazzeo and Antonini.* Contains over 100 color photographs. Oversized volume. *Counts as 2 of your 3 books.* **$25.00**

54995. THE ILLUSTRATED ENCYCLOPEDIA OF ARCHAEOLOGY. *Glyn Daniel.* **$17.95**

55007. THE IMAGE OF THE NEW WORLD. *Brotherston and Dorn.* The New World as seen through the eyes of its original inhabitants. Filled with myths and folklore. **$19.95**

59537. THE MAKING OF ADOLF HITLER. *Eugene Davidson.* **$17.50**

42529. DORA: The Nazi Concentration Camp Where Modern Space Technology Was Born and 30,000 Prisoners Died. *Jean Michel.* **$12.95**

46260. EUROPE BETWEEN THE SUPERPOWERS: The Enduring Balance. *A.W. DePorte.* **$18.50**

60555-2. MARITIME ARCHAEOLOGY. *Keith Muckelroy.* The ancient secrets of the ocean depths revealed by today's archaeologists. *Counts as 2 of your 3 books.* **$37.50**

62895. MONTAILLOU. *Le Roy Ladurie.* Portrait of medieval life: the passions, hopes and dreams of everyday people. **$20.00**

37326. CARNIVAL IN ROMANS. *Le Roy Ladurie.* A riveting study of culture conflict that led to disaster. **$20.00**

66280-2. THE ORIGINS OF THE COLD WAR IN THE NEAR EAST: Great Power Conflict and Diplomacy in Iran, Turkey and Greece. *Bruce R. Kuniholm. Counts as 2 of your 3 books.* **$27.50**

42219. THE FACTS ON FILE DICTIONARY OF EUROPEAN HISTORY: 1485-1789. *E.N. Williams.* **$22.50**

61645. THE MEANING OF HITLER. *Sebastian Haffner.* Answers the lingering questions surrounding Hitler's conduct. **$7.95**

4 Good Reasons to Join

1. The Finest Books. Of the hundreds and hundreds of books submitted to us each year, only the very finest are selected and offered. Moreover, our books are always of equal quality to publishers' editions, *never* economy editions.

2. Big Savings. In addition to getting 3 books for $1.00 each and the *Hammond Atlas of World History* FREE when you join, you keep saving substantially—up to 30% and occasionally even more. (For example, your total savings as a trial member—including this introductory offer—can easily be over 50%. That's like getting every other book free!)

3. Bonus Books. Also, you will immediately become eligible to participate in our Bonus Book Plan, with savings of at least 70% off the publishers' prices on any book offered in the Club.

4. Convenient Service. At 3-4 week intervals (16 times per year) you will receive the Book Club News, describing the Main Selection and Alternate Selections, together with a dated reply card. If you want the Main Selection, do nothing and it will be sent to you automatically. If you prefer another selection, or no book at all, simply indicate your choice on the card, and return it by the date specified. You will have at least 10 days to decide. If, because of late mail delivery of the News, you should receive a book you do not want, we guarantee return postage.

Library of World History J-AJ8
Riverside, New Jersey 08075

Please accept my application for trial membership and send me the three volumes indicated, billing me only $1.00 each. I agree to purchase at least three additional Selections or Alternates over the next 12 months. Savings range up to 30% and occasionally even more. My membership is cancelable any time after I buy these three books. A shipping and handling charge is added to all shipments.

3 books for $1 each.
Indicate by number the books you want.

Plus my free gift—Hammond Atlas of World History (52115)
A few expensive books (noted in book descriptions) count as more than one choice.

No-Risk Guarantee: If you are not satisfied—for any reason—you may return your introductory books within 10 days and your membership will be canceled and you will owe nothing.

9½" × 13½" hardcover atlas featuring over 100 maps illustrating the most significant periods and events in history.

females also rank higher than larger males if the discrepancy in size is not too great.

Although the female hyena's assumption of what are usually male roles in mammals is probably related to its evolution of sexual structures that mimic male organs, the link between these phenomena is not immediately clear. It cannot have much to do with sexual performance itself for, if anything, the female "penis" is a hindrance to copulation until its opening enlarges and its form departs from that of the male.

Kruuk suggests that the strong mimicry arose in connection with a common behavior in hyenas called the "meeting ceremony." Hyenas live in clans that defend territories and engage in communal hunting. But individuals also spend much of their time as solitary wanderers searching the landscape for carrion. To maintain the cohesion of the clan and to keep strangers away, hyenas must develop a mechanism for recognizing each other and reintegrating solitary wanderers into their proper clan.

When two hyenas of the same clan meet, they stand side to side, facing in opposite directions. They each lift their inside hind leg, subordinate individual first, exposing either an erect penis or clitoris, one of the most vulnerable parts of the body, to their partner's teeth. They then sniff and lick each other's genitals for ten to fifteen seconds, primarily at the base of the penis or clitoris and in front of the scrotum or false scrotum.

Kruuk believes that the female clitoris and false scrotum evolved to provide a conspicuous structure serving for recognition in the meeting ceremony. He writes:

> It is impossible to think of any other purpose for this special female feature than for use in the meeting ceremony. . . . It may also be, then, that an individual with a familiar but relatively complex and conspicuous structure sniffed at during the meeting has an advantage over others; the structure would often facilitate this reestablishment of social bonds by keeping partners together over a longer meeting period. This could be the selective advantage that has caused the evolution of the females' and cubs' genital structure.

Speculation about adaptive significance is a favorite, and surely entertaining, ploy among evolutionary biologists. But the question, "What is it for?" often diverts attention from the more mundane but often more enlightening issue, "How is it built?" In this case, speculations about adaptive significance have been in the literature for a long time, yet no one bothered to tread the obvious path for hypotheses of anatomical construction until 1979: What sexual hormones are maintained at what levels by female hyenas from conception to maturity? (See P. A. Racey and J. D. Skinner, "Endocrine Aspects of Sexual Mimicry in Spotted Hyenas, *Crocuta crocuta,*" vol. 187, *Journal of Zoology,* 1979, pages 315–26.)

Racey and Skinner found, in short, that two androgens (male-producing hormones) had higher concentrations in testicles than in ovaries of adult spotted hyenas (scarcely surprising). Yet, when they investigated levels of the same hormones in blood plasma, they detected *no differences* between males and females. One female contained two twin female fetuses, and both, despite their tiny size relative to their mother, contained about the same level of testosterone as adult females. Racey and Skinner therefore conclude "that high foetal androgen levels are responsible for the appearance of the male sexual facies in adult female spotted hyenas."

Confirmation for their hypothesis arises from their study of brown and striped hyenas, the other two species of the family Hyaenidae. Neither brown nor striped hyenas develop peniform clitorises or false scrotums. In both species, androgen levels in blood plasma are much lower for females than for males. (Aristotle, by the way, defended hyenas against the charge of hermaphroditism by correctly describing the genitalia of these other species—something of a dodge with respect to the spotted hyena, the source of the legend, but "the master of them that know" was right in any case.)

But why should high levels of androgenic hormones lead to the building of false penises and scrotums. The animals that construct them are still, after all, genetically female. How can female genes produce mimics of male structures, even under the influence of unusually high levels of androgenic hormones. A look at the developmental basis of sexual anatomy resolves this dilemma.

Mammals share a common pattern for the embryology of sexual organs, and we may therefore use humans as an example. The early embryo is sexually indifferent and contains all precursors and structures necessary for the development of either male or female organs. After about the eighth week following conception, the gonads begin to differentiate as either ovaries or testes. The developing testes secrete androgens, which induce the development of male genitalia. If androgens are absent, or present at low levels, female genitalia are formed.

The internal and external genitalia develop in different ways. For internal genitalia, the early embryo contains precursors of both sexes: the Müllerian ducts (which form the Fallopian tubes and ovaries of females) and the Wolffian ducts (which form the vas deferens—the ducts that carry sperm from the testes to the penis—in males). In females, the Wolffian ducts degenerate and the Müllerian ducts differentiate; males develop by the opposite route.

The external genitalia follow a markedly different pattern. Individuals do not begin with two distinct sets of precursors and then lose one while strengthening the other. Rather, the different organs of male and female develop along diverging routes from the *same* precursor. The male's penis is the same organ as the female's clitoris—they form from the same tissues, are indistinguishable in the early embryo, and follow different pathways later. The male's scrotum is the same organ as the female's labia majora. The two lips simply grow longer, fold over and fuse along the midline, forming the scrotal sac.

The female course of development is, in a sense, biologically intrinsic to all mammals. It is the pattern that unfolds in the absence of any hormonal influence. The male route is a modification induced by secretion of androgens from the developing testes.

The mystery of male mimicry in female hyenas may be solved by recognizing these fundamental facts of developmental anatomy. We know from the work of Racey and Skinner that female hyenas maintain high levels of androgenic hormones. We may therefore conclude that the striking and complex peculiarities of sexual anatomy in female spotted hyenas are simply, indeed almost automatically, produced by a single, underlying effect: the secretion of unusually large amounts of androgens by females.

The automatic nature of peniform clitorises and false scrotums in female mammals with high androgen levels

Additionally, I am interested in more specific information on:

Travel to Alaska by:

1. ☐ Car, Camper, Motorhome
2. ☐ Air
3. ☐ Cruiseship from California
4. ☐ Cruiseship from British Columbia
5. ☐ State Ferryliner
6. ☐ Motorcoach or Rail
7. ☐ Hotels & Motels
8. ☐ Lodges, Resorts & Cabins
9. ☐ Tours to Alaska from U.S. or Canada
10. ☐ Tours within Alaska
11. ☐ Camping in Parks & Forests
12. ☐ Fishing
13. ☐ Sightseeing & Attractions
14. ☐ Adventure Travel (guided hiking, trekking, boating, canoe & raft trips)
15. ☐ Fly/Drive Programs
16. ☐ Guided Birding & Wildlife Photo Trips
17. ☐ Winter Sports & Vacations
18. ☐ Alaskan Food Products
19. ☐ Conventions & Incentive Travel

We would like to learn more about people who are interested in Alaska. Please help us by answering these optional questions.

20. What year are you likely to visit Alaska.
    ☐ 1981, ☐ 1982, ☐ 1983, ☐ 1984 & beyond, ☐ I'm undecided about visiting Alaska.
21. Your age. _____
22. Level of education completed.
    ☐ Grade School, ☐ High School, ☐ College, ☐ Graduate School
23. How many would visit Alaska with you. _____ How many under age 10. _____
24. I plan to travel by ☐ Group, ☐ Independently.
25. In the past 3 years have you taken a vacation trip outside the North American continent? ☐ Yes, ☐ No.

Thank you!

Worlds of Alaska!®
Alaska State Division of Tourism
Pouch E-412
Juneau, Alaska 99811

If you read only one book this year, read this one.

The new 1981 edition of **"Worlds of Alaska!"** will help you plan the vacation of a lifetime.

"Worlds of Alaska!" contains 132 full-color pages of evocative description, action photography, invaluable information and thoughtful details that will help you make the most of your Alaska vacation. You'll discover all the places you want to see and all the things you want to do, carefully organized and graphically illustrated with photos, maps and charts. More than 1,200 visitor services are listed, and advertisements describe the most current offerings from Alaska's tour, transportation and lodging companies.

Read **"Worlds of Alaska!"** and discover a land of limitless adventure. You'll be ready for the best vacation ever—in Alaska!

Mail the reader reply card.
We'll send "Worlds" to you...FREE!

If the card has been removed, just write: Alaska State Division of Tourism, Pouch E-412, Juneau, Alaska 99811. (907) 465-2010

THE PEOPLE WITH MONEY ARE STILL SPENDING IT. BUT WITH INFINITELY MORE WISDOM.

We are indeed living in cautious times.

Even those fortunate enough to have a large amount of what economists call "disposable income" are disposing of it as prudently as possible.

And so one could find considerable irony in the fact that, even during the dog days of last year's crunch, the demand for BMW exceeded even the most optimistic predictions.

One could, that is, if it were not for the fact that the BMW is as appealing to those who know money as it is to those who know cars.

ENGINE TECHNOLOGY, A DECADE AHEAD OF THE COMPETITION.

In a desperate attempt to cope with the realities of the 1980's, many of the world's automakers have been forced to drastically rethink their engine technology.

Cutting cylinders, resorting to diesel fuel, tinkering with all manner of electronic devices.

Now, as any automotive expert can tell you, evolution is always preferable to revolution. So the fact that the engineers at BMW recognized the wisdom of such formerly exotic concepts as four and six-cylinder engines, sensible piston displacements and impressive power-to-weight ratios, literally decades ago, puts the BMW—and its owner—at a decided advantage.

In truth, the legendary performance capabilities of the BMW power plant are the result of years of evolutionary development—millions of miles of testing and refinement—on and off the great racecourses of the world.

STATE-OF-THE-ART ELECTRONICS.

At the turn of the ignition key, a computerized engine monitoring system (first installed by BMW in 1975) goes into operation.

With every engine revolution a computer receives and assesses signals from electronic sensors within the 6-cylinder engine itself. Then instantly determines the precise air/fuel mixture to be injected into the cylinder ports—optimizing emissions, fuel consumption and power development to a degree once considered merely within the realm of academic theory.*

THE OPTIMAL SYNTHESIS OF MAN AND MACHINE.

When you drive a BMW for the first time, you will experience a unique sensation: a total oneness with the car.

A standard five-speed transmission (automatic is available) affords the unaccountably unique opportunity to pick and choose one's own gears.

Its suspension system—independent on all four wheels—has a singular capacity for removing the drama from even the most unnerving road conditions.

Vital controls are within easy reach. The tachometer, speedometer and ancillary instruments are large, well-marked and totally visible.

RESALE: THE ACID TEST.

When all of the hyperbole has been expended, there is one brutally reliable way of determining a car's true value: how much of its original price it retains on the used-car market.

Seen in this revealing light no car in its category—not Mercedes 280E, not Jaguar XJ6, not Cadillac—equals the BMW.

According to the National Automobile Dealers Association's own 1980 used-car guide, for example, over the past 5 years the BMW 528i retained an astonishing 77.9% of its original price.

If you find the notion of owning a BMW more than a little intriguing, we suggest you phone your nearest BMW dealer and arrange a test drive at your convenience.

THE ULTIMATE DRIVING MACHINE.

is confirmed by several related examples. Female spider monkeys also have an enlarged clitoris and a false scrotum produced by overgrowth of the labial folds. Although their levels of androgen have not been measured (to my knowledge), they do use their enlarged clitoris in a male form of genital display and dominance. Better examples arise from unusual patterns of development within our own species. The adrenal glands also secrete androgens, usually in small amounts. In some genetic females, adrenals are abnormally enlarged and produce high levels of androgens. These baby girls are born with a penis and false scrotum. Several years ago a drug was placed on the market to prevent miscarriages. It had the unfortunate side effect of mimicking the action of natural androgens. Female babies were born with a greatly enlarged clitoris and an empty scrotal sac formed from the fused labia.

I believe that these facts of developmental anatomy must force a revision in the usual interpretation of male mimicry in female spotted hyenas. Evolutionary biologists have too often slipped into a seductively appealing mode of argument about the phenomenon of adaptation. We tend to view every structure as designed for a definite purpose, thus building (in our imagination) a world of perfect design not much different from that concocted by eighteenth-century natural theologians who "proved" God's existence by the perfect architecture of organisms. Adaptationists might allow a little flexibility for tiny and apparently inconsequential structures, but surely anything big, complex, and obviously useful must be built directly by natural selection. Indeed, previous literature on spotted hyenas has assumed that female sexual organs evolved directly for a definite function—as in Kruuk's speculation about the adaptive advantages of conspicuous external genitalia for recognition in the meeting ceremony.

But another scenario is possible and strikes me as more likely. I don't doubt that the basic peculiarity of hyena social organization—the larger size and dominance of females—is an adaptation to something. The easiest pathway to such an adaptation would be a marked rise in the production of androgenic hormones by females (these exist in small amounts in all mammalian females). High levels of androgens would entail complex secondary effects as automatic consequences—among them, a peniform clitoris and a false scrotum (we cannot, after all, label the very same condition in some abnormal human baby girls as an adaptation). Once they are present, some use might be evolved for them—as in the meeting ceremony. But their current utility does not imply that they were built directly by natural selection for the purpose they now serve. (Yes, I know that my scenario might be run in reverse: conspicuous female genitalia are required for the meeting ceremony, are evolved by enhanced androgen levels, thus yielding large female size and dominance as a consequence. I do, however, point out that under our usual preferences for seeing direct adaptation everywhere, my scenario would not even be considered. Indeed, it wasn't in the major works on spotted hyenas.)

My columns have the nasty habit of discoursing on funny facts of natural history, and then, only at the end, reaching the general argument that inspired the disquisition. This article is no exception, for I designed it to make a point about adaptation and the evolutionary analysis of form, not as a treatise on hyena penises.

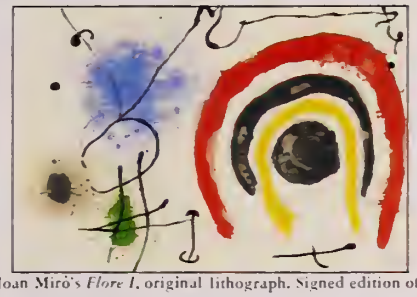
We do not inhabit a perfected world in which natural selection ruthlessly scrutinizes all organic structures and then molds them for optimal utility. Organisms inherit a body form and a style of embryonic development; these impose constraints upon future change and adaptation. In many cases, the direction that evolution takes is more a result of inherited patterns than of current environmental demands. These inheritances constrain, but they also provide opportunity. A potentially minor genetic change—a rise in androgen level in this case—entails a host of complex, nonadaptive consequences. The primary flexibility of evolution may arise from nonadaptive byproducts that occasionally permit organisms to strike out in new and unpredictable directions. What "play" would evolution have if each structure were built for a restricted purpose and could be used for nothing else? How could humans learn to write if our brain had evolved for hunting, social cohesion, or whatever, and could not transcend the adaptive boundaries of its original purpose?

In the second show of his *Cosmos* series, Carl Sagan told the tale of a Japanese crab that carries a portrait of a samurai warrior on its back. He argued that humans have built this face after their own image because local fisherman have been throwing back the most facelike crabs for centuries, thus imposing strong selection pressure for samurai look-alikes (the others get eaten). He used this example as his lead-in for a rapturous discourse on the pervasive power of natural selection.

I doubt this story very much and suspect that the conventional explanation is correct—that the resemblance is accidental and, at best, only slightly strengthened by human intervention. But even if Sagan were right, I believe that he is marveling at the wrong item (or at least failing to give equal time to another remarkable aspect of the case). I am most impressed by a crab's ability to do such an uncrablike thing in the first place—just as the capacity of an inherited developmental system to produce (and so easily) such marked changes in the sexual anatomy of female hyenas grabs me far more than any putative adaptive significance for the change.

The capacity of crabs to produce a face can have nothing to do with any selective value such a face might have since crabs do not routinely use this latent ability. It arises from several facts of crab biology: the bilateral symmetry of the carapace (corresponding by analogy with the bilateral symmetry of the human face), and the fact that many crabs are ornamented by creases along the midline (where a "nose" might form) and perpendicular to it (where "eyes" and "mouths" might be constructed).

The (probably accidental) production of a human portrait represents a stunning example of the evolutionary flexibility arising from nonadaptive consequences of an inherited design. Organic material is not putty and natural selection is not omnipotent. Each organic design is pregnant with evolutionary possibilities, but restricted in its paths of potential change. Fishermen might throw back selected starfishes with their five-part symmetry, or snails with their spiral design, for tens of millions of years and never carve a samurai into their hard parts.



Peter Medawar has described science as the "art of the soluble." Evolution might be labeled "the transformation of the possible."

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

What your home could have in common with the Met, the Tate, and the Louvre

M. William Schlesinger's *Terracescape*, original serigraph. Signed edition of 195.

Joan Miró's *Flore I*, original lithograph. Signed edition of 50.

Tjelda Michas' *Oriental Poppy*, original serigraph. Signed edition of 225.

Thom de Jong's *French Dinner*, original etching. Signed edition of 175.

In your own home, you can exhibit original work by artists who are represented in the world's great museums and galleries.

Artists like Calder. Chagall. Dali. Miró. Picasso. Vasarely.

At the Original Print Collectors Group, we offer moderately priced limited edition prints by these and other well-known artists.

Our offerings include signed original etchings, engravings, lithographs, woodcuts, and silkscreen prints.

Each print we offer is signed and numbered by the artist. Custom-framed. Accompanied by a certificate of authenticity and a full money-back guarantee.

And each print has been chosen not only for its beauty but for its investment value.

(Works by the artists we offer tend to appreciate, sometimes as much as 30% in a single year. Perhaps that's why *The Wall Street Journal*, *Business Week*, *Money*, AP, *Barron's* and UPI have quoted us as an authority on investing in art.)

For more information, send in the coupon. There's no obligation.

You'll find out about the special pleasure of owning original art, instead of just visiting it.

History in a lively and fascinating form . . .

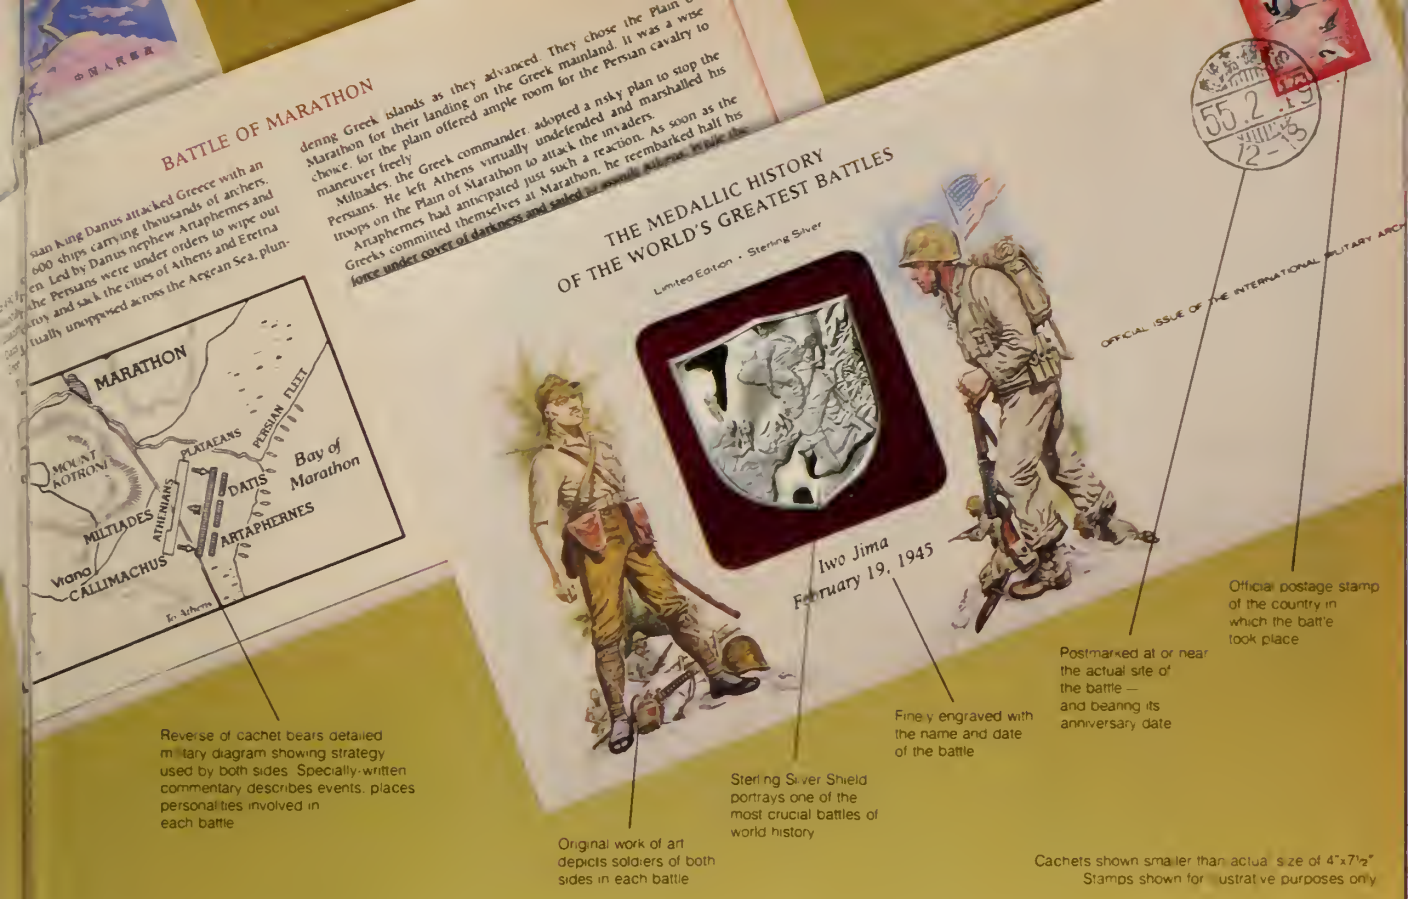
The great battles that changed the course of history—portrayed on unique Sterling Silver Shields mounted in engraved cachets

Each Silver Shield will be issued in its own engraved cachet. And each cachet will be officially stamped and postmarked at the site of the famous battle portrayed—on the exact anniversary date.

An official issue of the International Military Archives, Washington, D.C.

There is a world-wide limit of just 9500 complete sets.

Agincourt . . . Orleans . . . Trafalgar . . . Austerlitz . . . Waterloo . . . Yorktown . . . The Alamo . . . Gettysburg . . . Verdun . . . Dunkirk . . . El Alamein . . . Normandy . . . all sites of decisive battles that changed the course of civilization.



The names alone remind us that the history of the world has been shaped to a great extent by the struggle for power. But historians agree that there were *certain* battles that proved especially significant. Conflicts so worldshaking in their impact that they affected for all time the lives and fortunes of nations and peoples.

These are the great battles that will now be depicted in a new historical collection to be issued by the International Military Archives, Washington, D.C., the nonprofit association which is dedicated to the continuing study of world military history.

This collection will be *different* from any other because it will record these historical events in a distinctive form. *Sterling Silver Shields* that portray authentic scenes from the fifty most crucial battles in history.

These decisive battles include among others: Ancient Rome's greatest defeat—the Battle of Cannae—in which Hannibal destroyed virtually all the Roman fighting forces. The Battle of Hastings in 1066, which resulted in William the Conqueror being crowned King of England, the most decisive battle ever fought on English soil. The defeat of the Spanish Armada in 1588. The Battle of Yorktown, which ended the American Revolutionary War. The "Charge of the Light Brigade," one of the most infamous military adventures in history. The Battle of Verdun in World War I. D-Day—the invasion of Europe—greatest amphibious landing in world history.

Authentic scenes from these and many other great battles will be portrayed on Sterling Silver Shields created by the sculptors and engravers of The Franklin Mint. Each Silver Shield is crafted by impressing a

inely rolled sheet of sterling silver between wo matched minting dies. The result is a eautiful silver relief which captures the full cope of each battle scene in precise and ccurate detail.

Each Silver Shield mounted in an engraved cachet

o add to the educational value of this collection, each of the fifty Silver Shields will e housed in its own engraved cachet. The achet will identify the battle portrayed and ill bear an original work of art created by ne of the world's most renowned military rtists, Gerald Embleton. Each work—in ll color—will portray two soldiers, one om each side in the war represented. And ach figure will be shown in full military niform, just as he looked during the battle.

This full-color cachet art will complement the scene portrayed on the Silver hield—and provide a clearer, more vivid icture of the battle and the men who fought it.

Officially stamped and postmarked throughout the world

ach cachet will bear an official postage amp of the country in which the battle ook place. And it will be *canceled and ostmarked at the post office nearest to the tual site of that battle*. In the case of the rliest battles, extensive research was one to establish the location as accurately s possible, since even history books disgree on some of them.

Furthermore, each cachet will be *postarked on the anniversary date of the battle portrayed*. Again, in the case of the early battles, researchers have determined dates which are agreed upon by most historians in this field.

The reverse of each cachet will carry a *detailed military diagram*, showing the strategy employed by each side in the battle. In addition, a full description of the battle and a commentary on its significance will be included.

By examining each Silver Shield in its specially-designed cachet and, at the same time, referring to the military diagram and commentary—you will gain a greater understanding of the battles that changed world history. And, for younger people in the family, it will serve to enrich their understanding of these significant events.

Limited to just 9500 sets

The International Military Archives has placed a world-wide limit of 9500 sets on *The History of the World's Greatest Battles*. Once that limit is reached, all further subscriptions must be refused—and this collection will never be made available again.

Your application should be sent directly to The Franklin Mint, Franklin Center, Pa., which has been appointed by the International Military Archives to handle the distribution of the series as well as to produce the cachets. But to be sure of acquiring one of the limited number of sets available, enter your subscription promptly.

Your application should be mailed by February 28, 1981

ADVANCE SUBSCRIPTION APPLICATION

THE HISTORY OF THE WORLD'S GREATEST BATTLES

Limit: 9500 complete sets
Please mail by February 28, 1981

The Franklin Mint 20
Franklin Center, Pennsylvania 19091

Enter my subscription to *The History of the World's Greatest Battles*, consisting of 50 Sterling Silver Shields in specially postmarked cachets. The cachets will be sent to me at the rate of one per month, at the guaranteed issue price of $29.* each. I will also receive a collector's album at no added charge.

I need send no money now. I will be billed for each issue in advance of its monthly shipment.

**Plus my state sales tax*

Tropical Rain Forests: A Global Responsibility

If the world's rain forests disappear, people everywhere will suffer

by Peter H. Raven

Everyone who reads the popular press nowadays is aware of the extraordinary biological richness of the world's tropical rain forests and of the present fast pace at which they are being cut down. Less generally recognized is how little we know about the many species of tropical plants and animals and how the current destruction of the rain forests makes the need to increase our knowledge a pressing one. Of the estimated 3 million species of plants and animals in the tropics, only about 500,000 have been recognized and cataloged. In comparison, the temperate regions of the world contain some 1.5 million species, of which more than a million have been cataloged. A large majority of virtually every known group of organisms occurs in the tropics, making tropical forests the richest and most diverse association of plants and animals anywhere on the earth. About as many kinds of plants exist in the tiny country of Panama, for example, as in the entire continent of Europe, and nearly as many kinds of fishes—some 5,000—live in the drainage basin of the Amazon River as in the whole Atlantic Ocean. The diverse kinds of plants and animals in the tropics represent a potentially inexhaustible source of raw materials, only a minute fraction of which has been utilized or even tested up to this point.

The organisms that make up the ecological communities of the tropics are linked together in extremely complex ways. Fundamental processes such as energy flow and mineral cycling, which are complex and poorly understood even in temperate regions, are virtually unknown for the tropics. We do know that the rich and diverse communities of plants and animals that occupy tropical soils are relatively stable when undisturbed. They have remained stable for millions of years and are as appropriate to the climate and soils of their areas as the forests, swamps, and prairies in the United States are to theirs. When farmers plow up a prairie in the Midwest to plant crops, they are modifying a natural ecological system in order to create another productive, sustainable system. When agriculturists cut down a forest in the humid lowland tropics, they are often trying to accomplish the same thing. The many differences between the ecological processes involved in the two instances, however, have potentially tragic consequences for a large and rapidly growing portion of the human race. Once the sorts of forests that occupy most tropical areas are cut down, a reasonable agricultural yield is usually possible for only a few years. The cutover area, depleted of its fertility, often becomes a wasteland, with restoration to its original state or to use for any productive purpose virtually impossible.

Our ignorance about ecological processes in the tropics is compounded by our general lack of knowledge about tropical organisms. Although the vast majority are insects, mites, nematodes, fungi, and other relatively small organisms, we also have a great deal to learn about many species that are larger and belong to groups that are more familiar. To give just a few examples, some ten to fifteen thousand kinds of plants in Latin America, including many trees, have not yet been scientifically described and listed. These plants, which constitute perhaps an eighth of the total plants in Latin America, are generally viewed as a valuable resource, but as long as they remain unknown, they cannot be utilized rationally for human benefit. Similarly, many people are counting on manipulating the populations of fishes in the Amazon Basin and its tributaries as a way of increasing food production in the future. Competent students estimate, however, that approximately 40 percent of these fishes have not yet been recognized and

---

Director of the Missouri Botanical Garden in Saint Louis, Peter H. Raven served as chairman of the National Research Council's Committee on Research Priorities in Tropical Biology. Composed of scientists from many countries, the committee was concerned with the rapid destruction of the world's rain forests and the need to acquire basic scientific knowledge about tropical organisms and ecosystems. Last year, Raven presented some of the committee's findings before the Subcommittee on International Organizations of the House Committee on Foreign Affairs. This article is adapted from his remarks.

HISTORY REPEATS ITSELF

Again, we're only $15 a year

History repeats itself in the new year by offering you membership in the Museum of Natural History and 12 galvanizing issues of NATURAL HISTORY Magazine at last year's low price of just $15.

☐ YES, send me 12 months of NATURAL HISTORY for just $15 (I save $9 over the newsstand rate) and my museum membership which is included in my subscription.

cataloged. In other words, hopes are pinned on manipulating a system in which only somewhat over half of the elements have been registered, much less understood. Imagine trying to build a computer or an airplane from such a starting point!

Another example of how little we know about tropical ecosystems concerns the basic coupling relationships known as mycorrhizae. These symbiotic associations of fungi and the roots of trees are of essential importance in the recycling of minerals in tropical forests and hence in the stability and proper functioning of the forests themselves. The coupling is so tight that only a thousandth of the nutrients that reach the top layer of leaves on the forest floor penetrates even as much as two inches to the subsoil beneath. Understanding mycorrhizae is crucial to any successful conversion of these forests for other productive purposes; yet, how the relationships function has been demonstrated experimentally only within the past five years. Small wonder that our efforts to manipulate tropical forests for human advantage have so often met with total failure.

Greater knowledge about the tropics is certain to result in many discoveries that will promote human welfare. Approximately 45 percent of the medical prescriptions currently written in the United States, for instance, contain at least one product of natural origin, and as-yet-unknown plants might well contain chemicals that would assist in the cure for cancer. In addition, many of the important

Q. What is the WEBSTER'S NEW UNABRIDGED 20TH CENTURY DICTIONARY about?

A. It's about 2,300 pages and more than 4 inches thick!

For more than 40 years Webster's Unabridged Dictionary has served as an invaluable reference for students, teachers, businessmen, secretaries . . . and workers in all trades and professions. The reason is simple. Here is a dictionary that supplies the need for accurate and full definitions, correct spellings and pronunciations, full etymologies, synonyms, as well as other general and specific information.

A large staff of lexicographers and linguists has painstakingly edited and updated each definition so that it is clear, accurate, and readily understood in all its senses. Many new entries have been added, including recent additions to the language in the natural and social sciences, the humanities and other specialized branches of human knowledge.

un à bridged', *a.* not shortened; complete; specifically, designating a dictionary that has not been abridged from a larger work.
un ac cent'ed, *a.* not accented; specifically, in

The large, clear, legible type shown above (actual size) "makes this unabridged dictionary the most readable one in print."

. . . now own one of the finest reference books in the world at only ⅓ of its originally published price.

NEW DELUXE COLOR EDITION — **Includes Thousands of Illustrations Along With 32 Full Color Pages Plus a Full Collection of the Maps of the World**

Plus it contains these important supplements!

1. A Dictionary of Biography
2. A Dictionary of Geography
3. A Dictionary of Noted Names in Fiction, Mythology, Legend
4. A Dictionary of Foreign Words and Phrases
5. A Dictionary of Scripture Proper Names and Foreign Words
6. Abbreviations Commonly Used in Writing and Printing
7. Practical Business Mathematics
8. Forms of Address
9. Tables of Weights and Measures
10. Special Signs and Symbols
11. Presidents of the United States
12. Vice Presidents and Cabinet Officers of the United States
13. Declaration of Independence
14. Constitution of the United States
15. History of Canada
16. Charter of the United Nations
17. Air Distances between Principal Cities
18. Principal Geographic Features of the World
19. Commercial and Financial Terms

crops of the world have been brought into cultivation only recently. One example, the oil palm, widely cultivated only for the past fifty years, is now a multibillion-dollar industry.

In contrast to potentially useful wild organisms, many unknown species are potentially harmful. The brown leaf hopper, for example, is a small insect that caused several billion dollars of damage to rice crops in Southeast Asia during the past five years and reduced millions of people to starvation. A member of an insect group comprising more than 20,000 known species, which can be identified competently by only about a dozen people in the entire world, this pest was virtually unknown until it appeared by the billions in the rice fields of Southeast Asia three years ago. The pressure from pests and diseases in the tropics is generally so great that growing single crops in pure stands over any but the smallest areas is very difficult. Many such obstacles stand in the way of creating productive agricultural systems or reforestation projects similar to those that are common in temperate regions, and without basic knowledge of tropical plants and animals we will be unable to understand the potentially harmful ones well enough to prevent their depredations on crops and domestic animals.

Against this background, the tiny effort that is being undertaken to learn more about tropical plants and animals and the natural communities in which they live is embarrassing. Worldwide, there are no more than an estimated 4,000 scientists primarily concerned with studies of this kind; the total in the United States amounts to some 1,500 individuals. Probably no more than 1,500 scientists in the world are able to catalog and describe tropical organisms or are even competent to make professional identifications of them. The number of unknown tropical organisms—five out of six have never been seen by any professional student—amounts to a staggering total of some 2.5 million species, or about twice as many as all species described during the past 225 years.

An even smaller number of scientists throughout the world—no more than two dozen—are competent to supervise and undertake large-scale studies and experimental modification of tropical ecological systems. Of the handful of these individuals in the United States, no more than three are engaged in tropical studies at present. Notwithstanding this great lack, the ultimate success of every forestry and agricultural system being proposed for the tropics rests on an understanding of the functioning of the undisturbed ecological systems that are being replaced.

Gaining this understanding will cost money. Yet in the United States, the total expenditure in fiscal year 1979 for basic tropical biology was no more than $20 million. This small sum almost certainly represents more than half the total global funding; the tropical countries themselves are rarely able to divert significant amounts of money into research or even development. The collective human effort to learn more about tropical plants and animals and the associations in which they occur is very limited indeed.

The extremely serious nature of these deficiencies can be understood properly only when viewed against the background of tropical deforestation. The lowland tropical forests, which a century ago made up an area twice the size of Europe, have been reduced to about half their former extent. Every week, the remaining tropical lowland forest diminishes by an area about the size of Delaware, and every year, an area about the size of the island of Great Britain is removed. Such a rate of destruction, if applied uniformly around the world, would result in the disappearance of all unaltered tropical forest in approximately thirty years, but of course the rate is not evenly distributed. The National Research Council's Committee on Research Priorities in Tropical Biology, which published its report in June of 1980, estimated that within twenty years the only surviving extensive tracts of undisturbed tropical lowland forest will be those in the western Brazilian Amazon region and in Zaire in central Africa, and that even these will be altered and deforested during the first ten to twenty years of the twenty-first century.

This process of alteration is essentially irreversible for several reasons. First, it is closely connected with population growth in tropical countries, the great majority of which are growing so fast that their populations will double within twenty-five years. Since between 40 and 50 percent of the present population in most tropical countries consists of individuals less than fifteen years of age, even the immediate adoption of consistent and sustained population-control policies would not produce a stable situation until the latter part of the twenty-first century. By that time, the world would have a population of some 16 to 18 billion people, or about four times the present number. Second, the patterns of land use in tropical regions are such that only a very small proportion of the land is used to feed the hungry poor. In the United States, 7 percent of the landowners own 27 percent of the arable land. In Latin America, by contrast, 7 percent of the landowners possess 93 percent of the arable land, and since most of this land is planted with cash crops and export crops to earn foreign credit, the remaining 7 percent of the land must produce sufficient food for the vast majority of the people. International commerce, which guides the exploitation of the 93 percent of the land controlled by large landowners, plays a significant role in structuring the economies of tropical countries.

Poor people, denied access to arable land, cause about two-thirds of all destruction and alteration of tropical forest. These forest farmers cut out a section of forest and grow a crop or two before the soil deteriorates to the point where cultivation is no longer feasible. A variety of other factors are responsible for the remaining destruction of tropical forests. In Southeast Asia, the wholesale exploitation of forests for timber by foreign-owned corporations, which make little more than a gesture toward the replacement of the forests, is the major factor. In Latin America, the relentless effort to produce cheap beef for the United States and other developed countries is causing the disappearance of vast areas of forest. Ironically, while more than a quarter of all the forests in Central American countries have been destroyed in the past twenty years to produce beef for the American market, the average consumption of beef in those countries has declined steadily during the same period.

When they learn that tropical forests are rapidly disappearing, many people accept the destruction as warranted since they believe it will lead to the implementation of productive forms of agriculture that will help feed the hungry people of the world—much as the clearing of the forests in Europe and North America made possible the wide spread of productive agricultural systems in these regions over the cen-

Do you have room in your home for three wise men? They are Plato, Aristotle, and Marcus Aurelius...three of the wisest, wittiest, most stimulating minds that ever lived.

They still live...in the Five Great Dialogues of Plato, the Meditations of Marcus Aurelius, and Aristotle's On Man in the Universe.

All three books (regularly $22.17) can be yours for only $1.00 as your introduction to the Classics Club.

The Classics Club is quite unlike any other book club.

The Club doesn't offer best sellers that come and go. Instead, it offers its members a chance to stay young through great books that will never grow old. These books include Utopia by Thomas More; the works of Shakespeare; Benjamin Franklin's Autobiography; Omar Khayyam's Rubaiyat; Walden by Thoreau; and other fresh, spontaneous, even outspoken works that stretch your mind and sweep away the mental cobwebs that hold back most men.

You never have to buy any of these books. (To force you to buy a classic would be barbaric.) As a member, take only those books you really want to own. And, at any time, you may cancel your membership, without penalty or hurt feelings.

The selections themselves are remarkable values. They're carefully printed on expensive paper stock. They're hard-bound in matched wheat-colored buckram, worked and stamped in crimson, black, and 23-karat gold. And through direct-to-the-public distribution, we are able to offer our members these deluxe editions for only $7.39 each, plus shipping.

Interested? We'll send you the first three selections, Plato, Aristotle and Marcus Aurelius – all three for only $1.00 plus shipping.

We know what charmers these three wise men are. We're betting that you'll be so taken by them that you'll want to stay in the Club and meet some of their friends, including the greatest story tellers, philosophers, poets, and historians the world has ever known.

Don't send any money now. We'll bill you later. Just fill in the coupon below, now, while you're thinking about it and while the invitation still stands.

Mail coupon to The Classics Club, Roslyn, New York 11576.

LET THESE 3 WISE MEN INTO YOUR HOME.

LATER, YOU MIGHT LIKE TO INVITE THEIR FRIENDS.

THE CLASSICS CLUB ROSLYN, N.Y. 11576

Please enroll me as a member and send me at once Plato, Aristotle and Marcus Aurelius. I enclose *no money now*. After a week's examination, I will either keep my books and pay $1 (plus shipping) or return them. As a new member, I will get a complete list of titles from which to select the books I want. For each volume I choose, I pay only $7.39 (plus shipping). I may return any book, for full credit within 21 days and I may cancel my membership at any time. Note: Members accepted in U.S.A. and Canada only. Offer slightly different in Canada.

turies. Unfortunately, the comparison is totally without basis in fact. The current estimate of many Brazilian officials, for example, is that with currently available technology, only approximately 0.3 percent of the vast lowland forests in the Amazon Basin can be put into sustainable agriculture; about 95 percent of all the land in Brazil that is capable of sustained agricultural productivity is already under cultivation. The country now has some 90 million people, of which about a third are malnourished. Since the population is expected to double during the next twenty-three years, how malnutrition could be held even at the same proportionate level as it is today is unclear. Indeed, if the plans of the Brazilian government to alleviate the nation's acute energy shortage by planting sugar cane for the production of alcohol are implemented, approximately one-sixth of the currently productive agricultural land of Brazil could be taken out of production, a sacrifice that surely cannot be sustained in a country where a very large number of people are malnourished.

One of the most unsuitable purposes for which the tropical forests are being cut down is beef production. The kinds of cattle ranches that have been developed with such enthusiasm throughout Latin America during the past twenty years have proved ecologically unstable. The fertility of the ranch soils declines over a period of ten to twenty years until profitable cattle production is no longer possible. For most tropical soils, fertilizer—even when funds can be found to purchase it—does not restore fertility. Under the influence of the beating tropical sun and high precipitation, the structure of many tropical soils simply disintegrates, rendering them unable to retain nutrients. A number of tropical soils harden into cementlike layers, called laterites, that are impervious to the plow and essentially useless for agricultural purposes. Only much greater attention to understanding how undisturbed tropical ecological systems function and—through experimental manipulation of these systems—to finding ecologically suitable productive agricultural systems will succeed in alleviating such problems. Intercropping, for example, which involves the growing of several different kinds of crops together, will probably prove to be more stable in the tropics.

Regardless of whether they are developed wisely or unwisely, tropical forests are being cut down, and if their destruction and conversion is indeed irreversible, approximately one million kinds of plants and animals, or one-quarter of all that exist, will become extinct during the next thirty years, and possibly another million during the course of the twenty-first century. Such a rate of extinction is postulated on the destruction of the natural communities in which these plants and animals occur and also on the inability of many of these organisms to reproduce outside undisturbed tropical forest. The loss of biological diversity in the tropics as a result of these extinctions will have serious consequences for the human race. Every species is genetically unique. We cannot study an extinct species, we cannot use it, and we cannot develop it into something more useful.

Current conservation efforts, unfortunately, still tend to concentrate on a few obvious or well-known plants and animals, such as the Furbish lousewort, the snail darter, the elephant, or the tiger, while tens of thousands of other species go extinct without fanfare. Probably twenty times as much is spent annually to try to preserve the roughly thirty surviving California condors as is spent to find new kinds of tropical plants that might be important sources of food, fuel, or medicine. We must ask ourselves which kind of action has the greatest potential for alleviating human misery and helping to create a stable world.

By the end of this century, three-fifths of the world's population will be living in the tropics, and one-fifth in China. The remaining fifth will include all those people in the United States, Canada, Europe, the Soviet Union, Japan, Australia, New Zealand, temperate southern Africa, and temperate South America. The proportion of people living in the tropics will become progressively higher during the course of the twenty-first century. The projected picture for the world's tropical regions is by no means a promising one: current technology has not found a way to bring into cultivation more than 5 percent additional arable land in the tropics; the world's fisheries are badly depleted and declining; the roughly 400 million people who now make a living by clearing and farming small plots in tropical forests will have doubled in number and be essentially without any place to turn by the end of the present century; there is no obvious source for energy in most tropical countries other than burning up their forests, displacing productive agricultural systems with energy-producing crops, or developing their nuclear capabilities; and the total excess food productivity possible in temperate regions will be patently unable to feed the roughly 125 million people that will be added to the populations of tropical countries each year during the first part of the twenty-first century.

What happens in the tropics affects the entire world. For example, the shortages of many kinds of commodities, which developed countries formerly obtained from the tropics at very low prices, are already contributing to worldwide inflation and hence instability, and they will do so to a greater extent in the future. As a matter of self-interest and national security, all temperate, developed countries ought to begin to contribute substantially to the development of sustainable productive agricultural and forestry systems in the tropics.

We in the United States must adequately fund appropriate programs to learn more about tropical ecosystems and about how to use this knowledge for human benefit as directly as possible. To do this, we must take steps to increase the number of scientists competent to deal with such problems, both in the United States and in the countries directly concerned. Legal authority to conduct programs overseas must be granted to branches of government, such as the Department of the Interior, that can make a strong contribution in this area. Agencies such as the National Science Foundation and intergovernmental efforts such as the United Nations Man and the Biosphere Program, which have proved their ability to conduct studies in environmental biology, must be granted greatly increased funds for tropical research. In its foreign-aid programs, the United States must pay more attention to the importance of building up the research capabilities of the tropical countries themselves.

The countries of the world, developed and undeveloped, can prosper and exist in peace only in a relatively stable world. If we are to enjoy the benefits of global stability during the next century, indeed if we are to survive, we must seize the opportunities that are still available to us but which are diminishing every day. □

The 1981 Natural History Photographic Competition Is Open

The Grand Prize-winner this year will have a rare opportunity to photograph exotic wildlife with a close-up lens. And the winner may not even be a photographer. Let us explain about the special 1981 contest:

The Grand Prize will be an eleven-day trip, including airfare from New York and a berth on the yacht *Buccaneer*, to the Galápagos Islands. Many fearless creatures on those islands let photographers walk right up to them. The tour, sponsored by the American Museum of Natural History, will be led by two Museum scientists.

Seventeen cash prizes, totaling $3,500, will go to winners in seven categories, including a special new one, Historical Photographs. In this category, you need not be the original photographer, but you do have to own the picture and it should be more than fifty years old. So search your attic and old albums for prize-winning pictures that fit our three major categories.

The three major categories are Animals (including birds and bugs); Plants and Their Environment, and The Human Family. First prizes of $500 will be awarded in each.

In addition, Merit Awards of $250 each will go to the best entries in four categories: Photomicrography; A Sequence in Nature (up to five photographs); Historical Photographs; and Humor in Nature. Ten Honorable Mentions of $100 each will be selected from all entries.

The winning entries will be published in the July issue of *Natural History* and exhibited at the American Museum of Natural History.

THE RULES

1. The competition is open to everyone except employees of the American Museum and their kin.
2. Competitors may submit up to five previously unpublished entries (a sequence is considered a single entry).
3. The Museum acquires the right to publish, exhibit, and use for promotion the winning photographs. The Museum assumes no responsibility for other entries.
4. Entries may be transparencies or prints, either color or black and white, up to 8 by 10 inches. Each must bear the photographer's name and address. Entries must *not* be mounted in glass.
5. Enclose a self-addressed, stamped envelope for the return of entries.
6. Entries must be postmarked no later than April 1, 1981.

Pack them carefully and mail them to:

And good luck!

Children of the Hutterites

The goal of child rearing is voluntary submission of the will to the community

by Gertrude Enders Huntington

"All of us have by nature a tendency toward evil and to have pleasure in sin. . . . Children, however, know neither good nor evil."

Account of Our Religion, Doctrine and Faith Given by Peter Rideman, 1565

In 1963, when I embarked on a series of field studies in a Hutterite colony in Canada, I did not realize how very different the child-rearing practices of this communal Christian sect would be from those taken for granted in the New England college community in which we had been living. Otherwise, my husband and I might not have been so sanguine about taking our three children to an isolated, German-speaking community in which they would be immersed in a socialization process so thorough that it has maintained the Hutterite culture through some 450 years of persecution and protection, hardship and affluence.

My mother, a child psychologist and elementary-school teacher, came with us to the colony. The children had had little preparation other than time spent on Amish farms—and the family-centered culture of the Amish proved to be no preparation for the communal childhood they were about to experience. The Hutterite culture is rigidly age graded; not even as a child had I so often been asked, "How old are you?" Our three-generational family had a member in every age category except adolescence, but our fifth-grade daughter, because of her wider experience, was admitted to the edge of the adolescent's private world. As the oldest person in the colony, my mother was called grandmother by everyone. She was identified with the three grandparent couples. My husband and I were in the middle generation. Each of our children was in a different category: Abigail, nine, was a "German school" child; Daniel, who had his fifth birthday in the colony, was a kindergarten child; and Caleb, two, was a house child. Thus it was natural for us to participate in the various socially defined age grades and to experience personally the socialization process.

We were assigned a two-room house about forty feet from the nearest family (with whom we shared an outhouse) and about sixty feet from the nearest "long house," consisting of apartments for four families. The center of the colony had the feeling of a medieval village. It was bounded on one end by the communal kitchen, which housed the dining room, bakehouse, washhouse and bathhouse, and at the other end and slightly to one side was the public-school building, which was also used for German school and the daily church services. All buildings related to home and family were painted white with blue trim; those that served an economic function were usually painted red. All living buildings were built true to the compass, running due north and south or due east and west; the floor plan of the living houses has changed little since the sixteenth century.

The uniformity of the color and architecture, the physical proximity of the buildings, the grassy commons, the flowers around the houses, and the neat walks proclaim visually the orderly existence of the inhabitants. Time is measured out as discretely as space, and there is a proper activity for each moment of the day, each day of the week, each season of the year, and each stage of one's life. An individual's dress establishes sex, age, activity, and obedience to the rules of the colony. When it became evident that we were not simply visitors but participants, we were urged to take off our "ugly" clothes and put on Hutterite attire. The dress signified our willingness to accept our age- and sex-determined position in the colony and to abide by the rules. We became a part, first, of the visual environment, then of the behavioral environment, next the emotional environment, and finally, we almost became a part of the intellectual environment, usually

Jim Welch

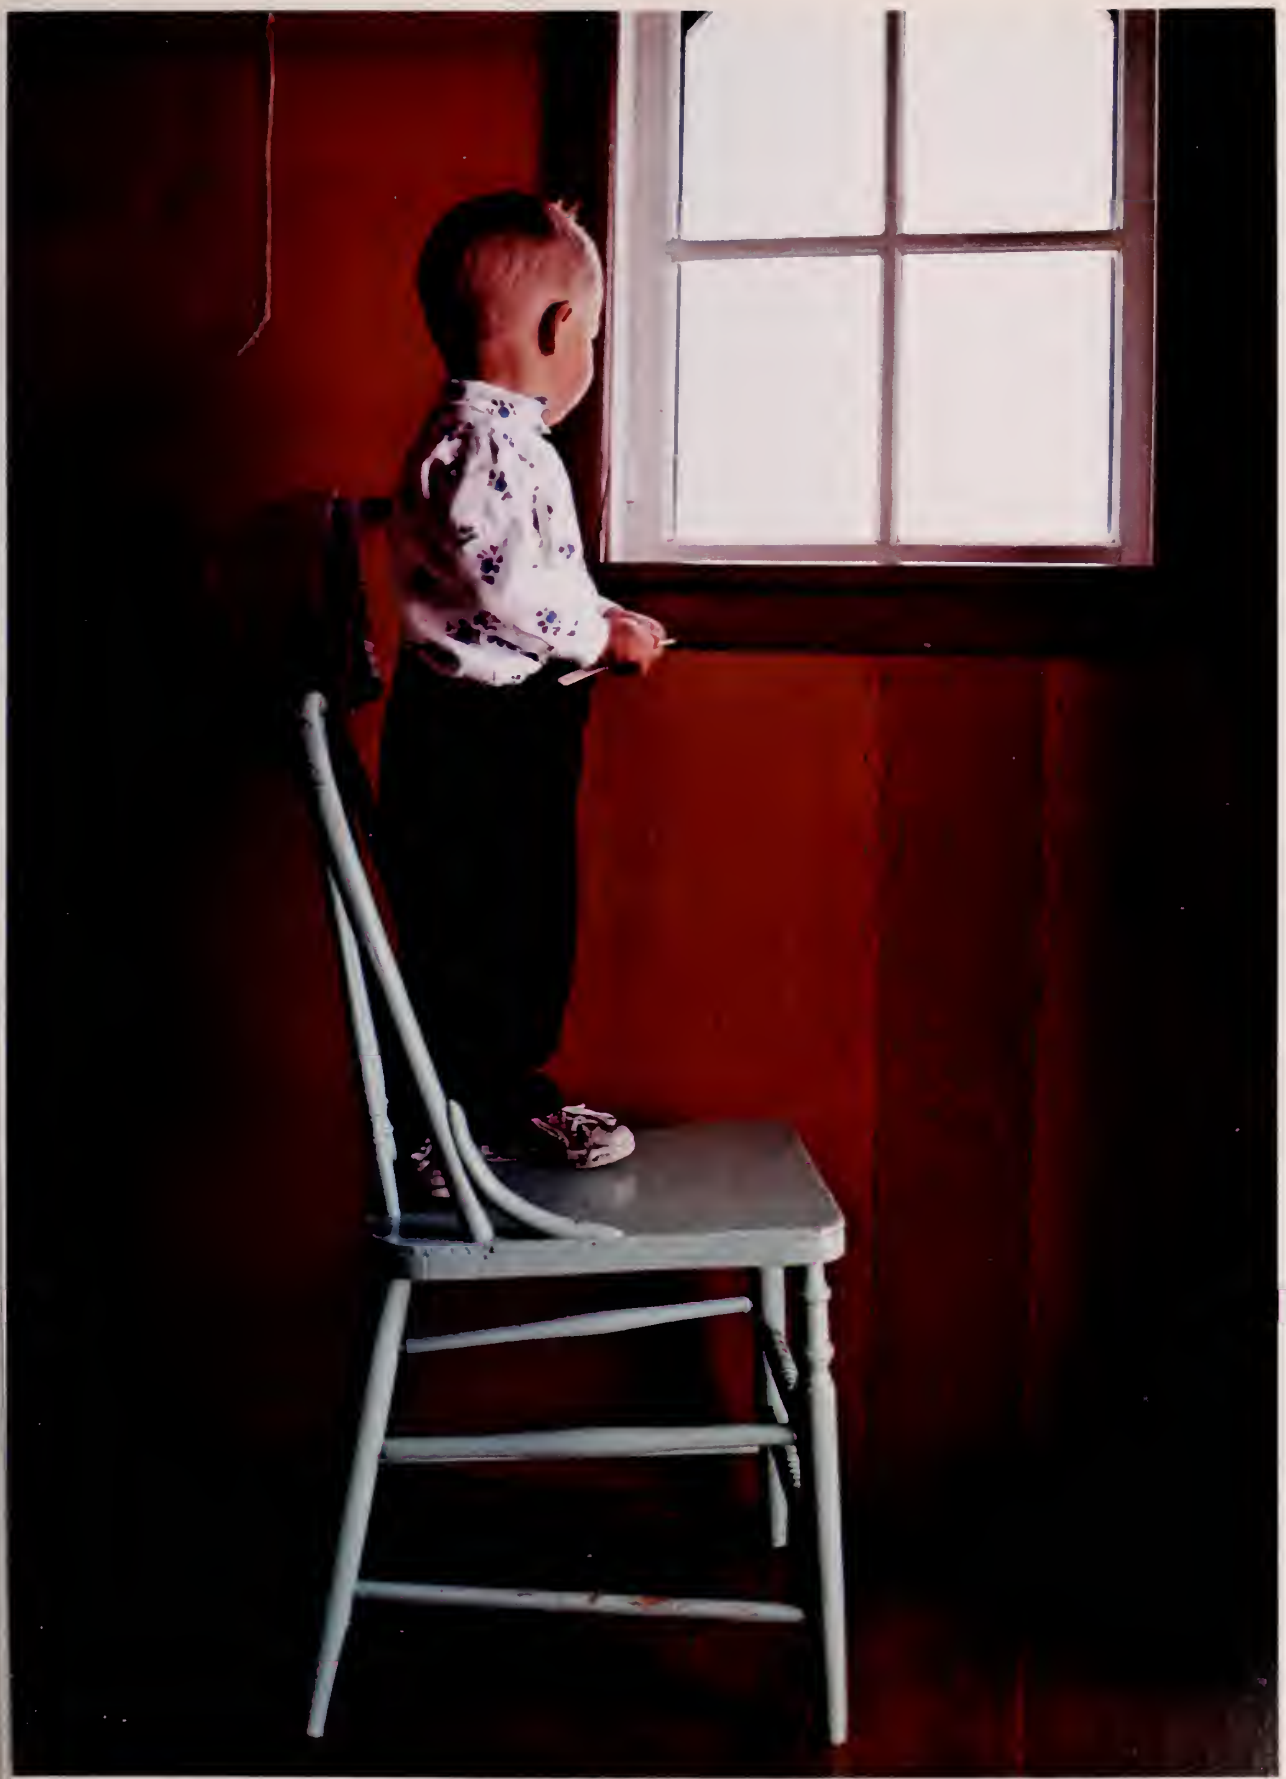
understanding but never quite internalizing the Hutterite world view.

This failure at the last step did not prove an insurmountable problem both because we were not permanent members of the community and because the Hutterites stress correct behavior over correct thinking. Their catechism asks, "What is inner shame?" The reply is, "When a man has sinful thoughts, which he should dispose of." It asks, "What is sin?" The answer is, "The transgression of the law." In a communal society, wrong thinking is bad, but if kept to oneself, is not disruptive; wrong behavior, no matter what the motive, is sin. And as participants, we were not to sin. We were helped to be good, for as the minister gently assured us, "You are fortunate to be living in the colony, for there are always one hundred eyes watching you."

The Hutterites, or Hutterian Brethren, live in discrete colonies on the plains of the United States and Canada. They migrated to the United States from Russia in 1874, having, it is claimed, been assured by President Grant that their absolute pacifism would not cause any trouble because "America would never fight in another war." Of the eight hundred Hutterites who came, about half took advantage of the Homestead Act and finally settled in dispersed family units; the other three to four hundred settled in three colonies in South Dakota. Through biological increase and by an orderly process of establishing daughter colonies, the population has grown to about 24,000, and the original three colonies have become 230. Today, colonies are located in Alberta, Saskatchewan, Manitoba, North and South Dakota, Montana, Washington, and Minnesota. Theologically, the Hutterites are Anabaptists, practicing adult baptism, total nonresistance, and apostolic communism. They trace their origin to a moment in the spring of 1528 when a cloak was spread before a group of religious refugees fleeing through Moravia, and each member of the group laid upon it his money and other worldly possessions. Thus, occasioned by necessity and sanctioned by religion, the practice of "all things in common" (Acts 2:44) was adopted as the Hutterite way of life. They called themselves Brothers, but were named Hutterians or Hutterites by outsiders after an early leader, Jacob Hutter, who was burned at the stake in Innsbruck in 1536. A minister's translation from the *Geschichts-Buch*, a history book kept by the Hutterite leaders through the centuries, describes Hutter's ordeal:

> After they had him captured, they tied a club in his mouth and transferred him to Innsbruck. They punished him and tortured him but he would not recant.... They proceeded to put him in ice cold water until he could not move. From there they put him in a warm room and lashed him unmercifully. They cut wounds into his body and poured alcohol into the wounds, lit it, and let it burn. But still he would not recant. After much suffering and torture, he was sentenced and burned at the stake alive.

The persecution of the Hutterites did not subside until 1551. By 1592, there were approximately ninety colonies in Moravia with an estimated population of twenty to thirty thousand. But by 1767 renewed persecution, war, and the Counter-Reformation had reduced their number to nineteen. This handful, joined by fifty-six Lutherans from Austria, fled to Russia, where they settled in 1770. When denied exemption from military service and the right to maintain their own schools in 1874, they emigrated to the United States. There conditions were favorable until the outbreak of World War I, when the Hutterites were harassed by their neighbors and Hutterite draftees were subjected to barbaric treatment. After months in solitary confinement, two North Dakota Hutterites who had refused to wear army uniforms died of physical mistreatment, malnutrition, and pneumonia. When the wife of one of the men asked to see his body, she was shown it—dressed in the military uniform he had so steadfastly refused to don. As a result of this episode, most Hutterites moved to Canada, where the majority still live. The men who died in prison during the First World War are remembered as martyrs to their faith.



Hutterites do not stress historical dates or even historical sequences, but stories of the martyrs and times of tribulation are copied by children in German school and are retold at informal gatherings where the children learn, and the adults remember, that it is better to "die the bitterest death, yea ten deaths, than to forsake the truth." Retelling their history reinforces their belief in the sinful and corrupt ways of "the world," their belief that this life is difficult and arbitrary and the true Christian must expect to suffer for his faith. The Hutterites have never believed their life to be utopian, viewing it instead as an exacting religious regimen that demands denial of self and of private property and absolute obedience to God and the community. A Hutterite work describes "a way of life that not even we who live it, always like, according to the flesh; but we know it is . . . the way the God of love wants his children to live on this earth. . . ."

The goal of child rearing among the Hutterites is the young adult's voluntary decision to submit himself to the church community. The Hutterites have been remarkably successful in achieving this goal by guiding their children through a series of socially defined age grades, each characterized by specific behavior and teaching.

During the first three years of life, the Hutterite child is known as a baby, or a house child, because it is fed at home and is primarily under the care of its parents. This is a privileged period in the individual's life and a time of intense socialization. Although little attention is paid to pregnancy, other than to maintain that the harder a woman works, the healthier her baby will be, and the role of the mother in the birth is de-emphasized (babies are viewed as a gift from God), the neonatal period is a very special time for both mother and child. The new mother is relieved of all colony responsibilities and given the full-time help of a mature woman. Typically, the woman's own mother comes from her home colony to care for and mother her daughter, who, in turn, cares for and mothers her new baby. The caretaker-nurse feeds and cares for the mother and her house children, does all her family work, and even sleeps with her at night, helping her twenty-four hours a day. Colony members and relatives from neighboring colonies come to visit the mother and to see the new baby.

Hutterites consider the neonatal child demanding and vulnerable but at the same time a great joy and a

During the first three years of life, the Hutterite child is known as a baby, or house child. House children are fed at home and are primarily cared for by their parents.

Craig Aurness

pleasure to care for. The mother is confident of her ability to supply her baby's needs and enjoys nurturing the completely dependent child. The baby wears a cap on its head, is swaddled with a blanket wrapped over its clothes, and is tied into a firm, straight bundle with a narrow cord woven just for this purpose. Swaddling is said to make the baby easier to handle and play with (that is, less easily injured and more enjoyable). A red ribbon or cord is tied onto the baby to protect it from the evil eye, from being fussy, from having colic. Its widespread use indicates the vulnerability attributed to small babies. When the child is four weeks old, the mother's caretaker leaves and the father takes over the nighttime care of the baby. For two more weeks the mother is relieved of colony work, then she is gradually reintegrated until, when the baby is thirteen weeks old, she resumes cooking for the colony and once again becomes a full participant. For the next three years, the colony schedule determines the time the baby will be fed, the time it will be played with, the time it will be left alone, and the time it should sleep.

Everyone in a Hutterite colony loves a baby. Children of both sexes will crowd around a baby to play with it. A child as young as two will be rewarded by being allowed to hold an infant. When the adults, especially the men, are not working, the babies are always held, and everyone who passes a very young child—adult Hutterites, colony members, and visitors—gives it cheerful attention. The baby is spoken to, picked up, tickled, played with. However, when it is time for church or the adult meal, the baby is promptly placed in its crib and the parents walk out. After seven weeks of age, a baby is always either in a socially stimulating environment or alone in its crib.

A child is believed to be completely innocent until it is observed to strike back or to pick up a comb and try to comb its hair. Either of these activities is believed to indicate that the child's level of comprehension is sufficiently high to understand discipline. The child is displaying self-will and understanding. If house children quarrel over an object, the object is removed; if they are quarreling for another reason, they are often told to kiss one another. Very young children will hit each other and then immediately hug and kiss, avoiding adult displeasure by quickly making up. An older house child may be strapped for refusing to go to someone other than its parents, for refusing to share food, or for being noisy and disturbing adults. Immediately after punishment, the crying child is comforted.

Hutterite women almost never take their house children with them when they are doing colony work. If the mothers are busy, the older toddlers, especially the boys, accompany their fathers and play near the place where the men are working, usually in the company of the youngest schoolboys. There is a united effort on the part of the colony, in which the parents cooperate, to wean the house children away from their parents and into the group. Most of the activities that are considered especially pleasurable, such as riding in a wagon or on the back of a truck, can be enjoyed only if the toddlers will leave their parents to join in the fun. When the little ones are in a group of children, however, they often become the butt of aggressive teasing.

House children are socialized to like people and to respond positively to every person (or at least every Hut-

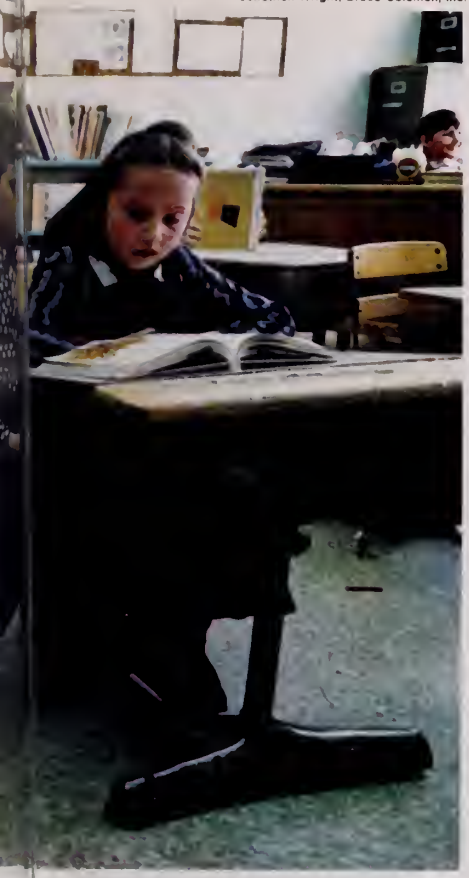
A baby's schedule becomes adjusted to that of the colony. An older child is assigned the task of baby sitter when the mother is occupied with colony work, eating, or attending church services.

terite) who comes within sight or earshot. They are taught to be aware of, and to respond quickly to, the wishes of others, but they are also taught not to initiate contact or disturb them. It is difficult to know what factors influence a child's development, but certainly Caleb, the house child we brought to the colony, has turned into an adaptable person who is comfortable with people and intuitively responsive to those around him. When we returned to New England and he began nursery school, he never spoke above a whisper in front of strange adults, but played happily with the children. He was a master at avoiding quarrels. By the time he was in kindergarten, he still rarely initiated contact, but college student observers reported he was the most sought-out child in the group. Caleb, who was at a socially favorable age stage, responded most positively to the Hutterites. For months, he asked daily when we would go back to live in the colony, and he has enjoyed each return visit, stepping naturally into the proper age- and sex-determined niche.

"Our kindergarten school is from three to six years. Here they learn to obey, sing, sleep, memorize, and pray together," explained a Hutterite minister. "We need the kindergarten," remarked a Hutterite kindergarten mother (teacher). "It helps the children and their mothers to realize that everyone should know his or her place." The status of the kindergartener is low. The child has plummeted from a relatively desirable position to the very lowest. Kindergarteners are considered willful and useless: "They can't do anything but memorize." The willfulness is somewhat threatening to a rigidly controlled people, and because the uselessness is no longer combined with complete dependency, it cannot be enjoyed by succoring caretakers. Verbal threats are used on children of this age for they are old enough to experience fear, yet not old enough to realize that the threats are empty. Most threats fall into one of two categories: those that teach that exclusion from the group is unpleasant; and those that teach that beyond the boundary lurks danger. Thus, a child may be warned that he will be locked in a hole under the house or given to a non-Hutterite visitor. If he opens a door, a bee in the closet will sting him, the dog in the (off-limits) barn will bite him, or a bear "outside" will eat him up. When it thunders, children are told that God is telling them they must be obedient.

Children pass the whole day in kindergarten, arriving before breakfast and, depending upon the convenience of the colony, leaving after an afternoon snack or after dinner. They learn to recite their prayers and hymns kneeling by the long benches, hands folded under their chins, the girls at one bench, boys at another. Rocking rhythmically, they recite very rapidly, the older ones doing so quite loudly. (This is the only occasion on which a kindergarten child may raise his voice.) No effort is made to explain the meaning of what is memorized. Children of this age are not permitted to touch any dangerous object. Until the age of six, they use only a spoon for eating and are not allowed to handle scissors, a knife, or a pencil. Several kindergarten children were strapped for playing with our five-year-old son's hammer and saw.

To the Hutterites, it is obvious that children have stubborn wills that must be broken; kindergarten helps teach the children not to be stubborn or willful. As one kindergarten mother explained when she swatted a child



English school is where the child learns arithmetic, science, and the ability to read and write in the English language. The curriculum is similar to that taught in other rural schools.

who was licking his boot, "He's only three years old and still very young. He'll need many *britschen* before his will is broken." Children must obey the person in charge; they may not leave the kindergarten yard; they must share; they are not allowed to fight, quarrel, or hit; they are not to call one another names or use "bad words." In a *Gemeindordnungen* ("colony rules") of 1812, the members are reminded that "it is very sinful and rude" to call each other such insulting and contemptuous names as "pig" or "dirty dog." Yet the first Hutterite words our five-year-old used spontaneously were those for "you pig" and "you dirty dog."

The kindergarten mothers use encouragement, praise, and rewards with the children. The little boys are told to "eat up! eat up! so you can drive a Massey [tractor]." A child who has been helpful may have the privilege of going with the kindergarten mother to bring the food from the kitchen. A child who has behaved very well may be the first to be dismissed in the afternoon. A small child may be comforted with a little candy from the kindergarten mother's pocket, or a group of children may be promised a walk if they are good. Punishment includes scolding, switching, and threats. Some kindergarten mothers feel that a leather strap is too cruel for children and makes them tough without correcting them; a willow switch is better. The children are given only a couple of switches, and those older than four rarely cry. When a three-year-old was crying after being punished, one of the five-year-olds remarked, "We're already tough, we don't cry anymore, only Michael does." (Michael had just begun kindergarten.) The children are not punished in anger or vindictively. Their kindergarten mother, who as the name implies, regards them almost as her own children, is confident that she is helping the children grow into worthy Christians.

Kindergarten introduces children to their peer group and teaches them how to function in it. "They learn to obey, sing, sleep, memorize, and pray together." At an age when the child in North American society is developing individuality and a concept of self, the Hutterite child is placed in a setting that minimizes self-assertion and self-esteem and maximizes identity as a member of a group. Of all the age groups within the colony, the kindergarteners experience the most restricted, most regimented, and least varied program. Physically, the children spend virtually the whole day in one little building and small enclosed yard; they are cared for throughout the day by only one adult. There are no vacations during the school year except for half-day sessions on weekends and church holidays. The children learn to tolerate a restricted environment. They are rewarded for cooperative, docile, passive responses to correction or frustration. After entering kindergarten, the child's parents and the adult colony members no longer will accept the varied range of behavior permitted the child who is still considered to be a baby. The child must now be quiet around adults, even cry quietly. Visitors from other colonies do not greet kindergarten children or German-school children. Adults rarely play with them and no one wants them around. As a Hutterite mother said of her kindergarten-age son, "I'd certainly like Danny less if I had to see any more of him." The children can easily interpret these changes as rejections. But even though they have fallen from the "garden of Eden" status of house children, they have started the steady, rewarding ascent that leads to full, responsible membership in the colony.

Our kindergarten child, Daniel, vigorously protested his low status in the colony, did not identify with his Hutterite peer group, and saw no reward or purpose in the long climb to colony membership. He did not even want to drive a tractor, then or when he grew up. We protected him somewhat from full colony participation by not sending him to kindergarten regularly and by discouraging other adults from administering physical punishment, but we could do little to protect him from the older children. By Hutterite standards, he had not been sufficiently weaned from his mother and grandmother for he spent more time with the women in the family than is typical for Hutterite boys. The colony tried

Jonethen Wright, Bruce Colemen, Inc.

to integrate Daniel into the group, but his stubborn will had not been broken; he did not passively accept punishment at the hands of the older boys. He responded to teasing with anger; if an older boy called him a bad name, he responded in kind. The crueler the children were to him, the harder he fought back and the louder he yelled his objections—a response that is totally unexpected (and altogether unacceptable) in a Hutterite child of his age. The colonists considered him a woeful example of a child whose will was not broken at the proper time. His situation improved after his father arrived and he could go around the colony with the school-age boys who spent part of the time working with their fathers or brothers. Nonetheless, today he deplores the Hutterite way of life. Since we left the colony he has returned only for very short, uncomfortable visits. On the other hand, it may have been in the colony that he learned to minimize physical discomfort. He still ignores public pressure. He knows that if one is willing to pay the price, one can go against convention and probably survive; the group does not have to determine one's values or behavior.

"Just as iron tends to rust and as the soil will nourish weeds, unless . . . kept clean by continuous care, so have the children of man a strong inclination towards injustices, desires and lusts," wrote a Hutterite leader in 1652. And today the German-school teacher reminds his charges, "Good children are obedient, peace-loving, and God-fearing." Hutterites believe that children are inclined by nature to misbehave, but this belief does not mean that misbehavior should be tolerated. Rather, the responsibility for the children's behavior is placed on the adults, whose duty it is to watch over the children. Although these adults customarily use physical punishment to elicit good behavior, there are no battered or neglected children among the Hutterites. As children do

In German school, children learn to read German and write in Gothic German script. They must also memorize biblical passages, hymns, and innumerable episodes from Hutterite history.

Young Hutterite girls often create a secret world confined to a locked wooden chest. Here are found bits of the temporal world, such as cosmetics, cheap perfumes, sheet music, jewelry, and suntan lotion.

not know the difference between right and wrong, it is determined for them; they are taught "rules," not "ethics."

On his sixth birthday, the kindergarten child is taken by the kindergarten mother and handed over to the German-school teacher. Until his fifteenth birthday, the child will be under the care of this adult, eating all meals with the peer group, attending German and English school with them, and doing colony work assigned by the German teacher. The children are taught table manners and work roles. They learn to read German and to write in the Gothic German script. They learn to count, to be proficient with weights and measures, and they memorize innumerable biblical passages and hymns, as well as episodes from Hutterite history. German school is ungraded, and the children sit by age and sex. Material must be covered in a certain order and learned thoroughly, but children work at their own speed. Slow learners are praised as frequently as fast learners. Diligence, not aptitude, is demanded, and only a certain kind of questioning is considered acceptable. For instance, six-year-old Susanna received three slaps on her hand from the German teacher when she asked, "Why should I?" It would have been all right if she had asked "when" she should do a task, "how" she should do it, and "if" she should do it, but if told to do something, she must be obedient and not question why.

Children are not pushed to grow up either intellectually or morally. They are not taught self-discipline for it is not their prerogative to decide what is right; they are to do what they are told and those in authority will watch over them and punish and protect them. Similarly, children are not made to feel guilty; it is only natural for a child to sin and therefore it is not "his fault" that he misbehaves. Our school-age daughter angrily complained how unfair it was for us to expect "good" behavior when she was out of sight—none of the other children had to behave when they were not being watched.

Punishment by the German teacher is administered uniformly and fairly. Everyone receives the same punishment for the same offense. When several of the boys were late to German school because they were catching polywogs, the consensus was that the three straps they received were well worth the fun. They had known they would be late and what the punishment would be. The children were not lectured about their behavior, which Hutterites consider typical for boys, who naturally prefer polywogs to memorizing. The punishment was payment for the misbehavior, wiping the slate clean. Everyone knew that when the boys were older, they would be less interested in polywogs than in their colony responsibility. No one moralized, no one worried, no one was offended. A young child angry about being punished may tattle on other children, who will then be strapped as well, and they in turn may tell something on the first child, who will receive a second strapping. When the children are alone, they will pick on the original tattler, however, and so by the time the children are seven or eight, they rarely tell on one another. The peer group can punish more severely than adults, but it can also protect. When the children present a united front to authority, they can often avoid punishment.

The sisters in each family have their own playhouse and there are ever changing cliques determining who can play in which house. Social fickleness teaches the girls the unpleasantness of being excluded. The cliques quickly coalesce, however, to present a united front before the boys or the adults. The children's play reflects the community's de-emphasis of physical pain and complaining. They play games such as "whistle when it hurts" and invent spontaneous games of physical stress and daring. Their play is characteristically vigorous and often entails a great deal of roughhousing. Boys don't play with girls, except in group situations where conflict and competition between the sexes is the typical pattern.

When our house child, Caleb, returned to the colony as a schoolchild, he reported that German school was better than English school; the German teacher was kinder and more impartial than the English teacher. Caleb was more comfortable being swatted by the German teacher for playing with polywogs than being praised by the English teacher for a good recitation. He was comfortable and happy in the vigorous boys' groups, working hard and playing hard, knowing that breaking the rules meant punishment, but experiencing a kind of pack freedom where undue demands are not made on the growing child.

During our first summer in the colony, our schoolchild, Abigail, quickly internalized the rules of dress and conduct and instructed us accordingly. She identified closely with her peer group and participated fully in German school and Sunday school (except that she did not answer questions on the sermons), did all the colony work expected of children her age, and regularly waxed the floors for a woman

Jonathan Wright, Bruce Coleman, Inc

with a large family but no school-age daughter. Abigail learned to act shy in front of adults and to show no other emotion unless she was alone with the children, joining in their rough and boisterous play. Wholly submerged in colony life, she found it difficult to distance herself sufficiently to comment on her activities. However, the energy it took to "become" Hutterite was indicated by a request she made the only time our family was together outside the colony: "Drive slowly, it is so easy to breathe out here."

Perhaps because of her experience in the colony, today in almost every situation, Abigail picks up behavioral cues and notices how people are relating to one another. While she was living in the colony, Abigail did not want to differ from her peers. She passively accepted the "pruning" given all the "young, tender plants" as she learned the rituals that insure the smooth social functioning of the group. But because she was an outsider, she knew it was her choice to accept the pruning passively. It never occurred to her peers to exercise their choice, and she realized that they were unaware they had a choice. Having lived with people socialized not to recognize their individual freedom has made her sensitive to the lack of awareness of the freedom of choice exhibited by many individuals in our own culture. As she learned to see with Hutterite eyes, she realized how differently the world can be viewed and how from the same set of facts different conclusions can be drawn.

The most important birthday for a Hutterite is the fifteenth, for on that day the schoolchild becomes an adult, moving from the children's dining room to the adult dining room, from the children's group into the adult work force. Even the word used to identify the child changes: the *mandel*, "little man," becomes a *buah*, "boy"; the *dindla* becomes a *die-en*.

The adolescent years are a time for exploring boundaries. As long as their behavior during this period does not interfere with the young people's work, adults, remembering their own youth, accept it.

As this is a change involving a single individual, it is not celebrated by the colony. There is no party, no formal recognition, only orderly progress to the next step. The colony does not administer physical punishment to those older than fifteen, and so the other children teasingly tell their schoolmates that they will get a final whipping on their birthday. Instead the German teacher gives the fifteen-year-olds several religious books, discusses their future roles as adults, and emphasizes the importance of giving cheerful obedience to those who are

above them. Gradually, at the colony's convenience, new adults are given various gifts that reflect their altered status and are needed in their new roles. Both boys and girls are given a locked wooden chest in which to keep personal belongings. The boy receives new cloth for good suits and shirts, the girl material for dresses. Boys are handed work tools, which they are responsible for keeping in good working condition: a spade, a pitchfork, a hammer, a saw, and in some colonies, a spoon with the individual's name inscribed on it. The girls receive equipment that they will care for and use for colony work: a scrub pail, a paintbrush, a hoe, kitchen knives, a broom, knitting needles, and in some colonies, a rolling pin. For the next two years the young adult occupies an apprentice position before being assigned specific responsibilities, such as taking charge of a small tractor or doing the colony baking. These boys and girls constitute a mobile labor force that can be deployed throughout the colony as needed (in jobs considered suitable to their sex) and may be sent to other colonies to help during a time of need. The boys in this group do most of their colony's hard labor and enjoy the opportunity to demonstrate their strength and stamina.

Hutterite young people are in transition between childhood and adulthood. The colony recognizes both aspects of their identity. Physically, the young people are adults who can work responsibly with other adults. Religiously, they are children who must attend Sunday school and memorize and recite weekly verses. Emotionally, they vacillate. Appropriately, this period is sometimes called "the in-between years." Certain limited disregard of colony mores is expected, but moodiness or poor work performance is not tolerated. A good young person is "always obedient and never talks back."

The in-between years are a time for exploring the boundaries, for flirting with the world and learning about

Women are not involved in economic competition with the outside world. When ducks or geese are raised for colony use the women and children care for them; if they are a cash crop, men are in charge.

that which will later be rejected. Most young people occasionally watch TV, have photographs taken (Hutterites believe no one should make a graven image), and even own cheap cameras. From hidden transistor radios, they memorize popular songs. Quite a few of the boys own wristwatches and occasionally a boy will smoke secretly. To earn extra money, some boys trap during the winter and sell the furs or moonlight on neighboring farms. The girls have colored nail polish and may use it to paint their toenails, which are hidden under heavy, black-laced shoes. They have perfume and dime-store jewelry, fancy underwear and perhaps a pair of slacks—all of which are forbidden in the Hutterite community. The in-between years are a period of limited self-realization. A young man may even leave the colony for a few weeks, several months, or sometimes for a couple of years. In most cases, however, he is a "tourist" in the outside world who plans to return to marry and raise his family within the disciplined community.

There is a tendency, especially pronounced among the girls, to create a secret world during this time. As long as the make-believe does not in-

Robert Weinreb

Hutterite boys and girls make up a mobile labor force that is deployed throughout the colony as needed. The children perform tasks that are considered suitable to their age and sex.

terfere with their work and is not flaunted, adults tacitly accept it and, remembering their own youth, are indulgent. Sometimes the secret world is confined to a locked wooden chest; sometimes a corner of the attic is made into a personal microcosm. Here are stored bits of the temporal world—photographs, sheet music, suntan lotion, souvenirs. These artifacts represent, however meagerly, what the individual has the freedom to pursue or the freedom to renounce. They represent the world outside the colony, the self in its indulgent, vanity-pleasing aspects. As individuals mature and measure these trinkets and conceits against the full life around them, they generally find that the satisfactions received from active participation in the colony far outweigh those of self-indulgence. The Hutterite self-image requires colony identification.

During the last year or so of their status as young people, adolescents are expected to show by their proven works—in other words, by their daily behavior—that they can adhere to the rules of the colony. When they have displayed by their actions and know with their heart and mind that they cannot continue as irresponsible children, they willingly and humbly request baptism, so that they may become true members of the colony. The goal of the Hutterite system of child rearing is achieved.

Throughout the centuries, Hutterites have developed subtle ways to elicit social conformity. Not only our children were exposed to intensive socialization—so were we. The first step was our dressing Hutterite. Accepting the symbols of the culture reinforced acceptable behavior. My husband had his hair cut and his beard trimmed by a colony member, indicating not only that he was a married man but that he accepted the rules of the community. My mother and I wore long, dark dresses with high necks and long sleeves, and even when we were working in the ninety-degree temperature we kept our heads covered with a cap, which buttoned under the chin, and a closely woven, double-layered, black polka-dot scarf. The minister quoted to us, "By their fruits ye shall know them," which was interpreted to mean that by dressing correctly, we indicated our acceptance of our proper place in the universe. When my mother commented that she did not

After the age of three, the house child will slowly be weaned away from the nuclear family and start the steady ascent to full, responsible membership in the Hutterite colony.

see why we could not just wear the cap and take off the head scarf when the weather was so hot, she was told, "We can't expect to be comfortable here and there both." (If you are comfortable in this life, you should not expect to be comfortable in the hereafter.) When she found many of the small regulations pertaining to the lower status of women irksome, members of the colony implied that perhaps she was forgetful of them because of her advanced age. This was an effective means of soliciting conformity from a professionally competent child psychologist. With me, they implied that perhaps the colony work was too demanding. As status is closely tied to one's ability to work hard, long, and fast, I shaped up and conformed. Because by Hutterite standards my husband (an art historian) was low on skills, he worked with the older adolescent boys, as well as with the married men. When they felt he was not paying enough attention to his job, they would call out the number of strokes it took him to sink a nail.

The pressure on us to conform could not be resented because it grew out of the Hutterites' deep conviction of the rightness of their way of life and out of their acceptance of us. Patiently they instructed us and helped us. I learned to pluck live geese and was helped to create a spotless, flower-accented house to welcome my husband to the colony. We were reminded that being a nice person had nothing to do with where we would spend eternity; we were either "in the ark" or we were "not in the ark." The depth of their concern and generosity was evident when they offered to come any time to start a community with us. Although they do not go out as missionaries, the Hutterites were willing to send their centuries-old sermons with us. Twentieth-century individualists, we were privileged to share the details of everyday life with people who have all surrendered their own will and given themselves with singleness of heart to God and church. □

Craig Aurness

The Eskimo vs. the Walrus vs. the Government

Hunting walrus has traditionally provided Eskimos a means of subsistence. But should subsistence include color television, snowmobiles, and alcohol?

by Dan Strickland

The walrus-skin boat glided silently forward, its pliable bow pushing small chunks of ice to either side. The Eskimos were tense but ready, their eyes directed ahead, gloved hands checking rifles and cartridges.

"Take your cap off!" John whispered fiercely. "Walrus don't like red. They see that, they're gone."

I slid the wool cap from my head and stuffed it into a pocket, feeling immediately the gelid touch of the wind.

It was after midnight, but the Arctic sun hung stubbornly above the northern horizon. Its rays turned the pack ice to amber and seemed to gild the sea itself with a placid sheen. Across the disintegrating pack ice of this late spring night Little Diomede Island rose abruptly, a stark sentinel at the

Chlaus Lötscher

Hauled-out on an ice floe off Little Diomede Island, left, a herd of walrus takes its rest. John Iyapana, captain of the umiak, leads a crew of fellow Diomeders on one of their annual spring walrus hunts, below.

John W. Matthews

crossroads of the Bering and Chukchi seas off the coast of western Alaska.

John gripped my arm and directed me to one side of the umiak. "We'll approach in this way," he explained, illustrating with his hands. "Broadside, so everyone can shoot."

The umiak skirted a cake of ice and came suddenly on the walruses. Twenty massive bulls lay together on a large ice floe—grunting, bellowing, thrusting at each other with their heavy ivory tusks. Only one or two of the more wary animals glared at us as we drifted in closer and closer. We were scarcely fifteen yards away.

Edgar used the stilled motor as a rudder and the umiak turned slowly broadside to the walruses. John whispered a signal and firing erupted from the boat. There was a moment of confused hesitation before the enormous bulls began lumbering toward the edge of the ice. They slipped gracefully but ponderously into the sea, churning the water into a frothy turbulence.

Four bulls remained, motionless in death. The umiak's bow touched the ice and the crew leaped nimbly onto the floe. Long knives, carried in scabbards made from the skin of the *oogruk,* or bearded seal, were drawn and sharpened on whetstones. With a rapidity and skill born of years of experience the Eskimos laid the carcasses open and cut them into pieces that could be lifted easily, dragged to the skin boat, and heaved aboard. All the meat from the animals was salvaged, including the intestines, stomach, liver, and heart. Four sets of white ivory tusks were thrown in last, on top of the steaming meat. As we pulled away, little more than a red stain colored the ice.

The walrus-hunting season—heralded by the annual spring retreat of the ice to more northern waters—was only beginning for the Diomede people. The village was emerging from winter with a limited supply of fresh walrus meat. On these early hunting trips, great quantities of walrus and seal are brought back to the village by the crews. This meat is distributed among the people to fill their depleted caches. I wondered how much meat would be retrieved as the season progressed and greater numbers of walrus were harvested.

In 1977 and again in 1978, while working for the Alaska Department of Fish and Game, I visited many

Eskimos unload walrus meat and tusks from their umiaks, right. The bounty will be transported via snowmobile to the village on Little Diomede Island. A hunter, below, hacks the ivory tusks out of a walrus skull.

Fred Bruemmer

of the state's coastal and island villages to gather specimens from the walruses and seals harvested in the spring hunts. Hunting with the Diomede people gave me a vivid picture of the world in which they live, a world dramatically different from any I have known. In particular, I learned that the Eskimos have a perception of animals—indeed, of life itself—that is all their own.

In August 1728 Vitus Bering sailed through the strait that Capt. James Cook would name for him fifty years later. Bering christened two islands in the strait after Saint Diomede. Despite their proximity (less than three miles apart), Big and Little Diomede are split by the international dateline and mark the boundaries of two different worlds. Big Diomede belongs to the Soviet Union; Little Diomede, called Ignaluk by the inhabitants, is the northwesternmost extension of Alaska and has been home to a hardy group of Eskimos for centuries. Although many of these people came originally from Siberia and Big Diomede, visits between the islands have been curtailed since 1948.

The Little Diomederers are embroiled in a newer and more explosive issue than détente between governments. They are a hunting people. The waters of the Bering and Chukchi seas are treacherous, but abundantly rich in marine life. Walruses, seals, polar bears, whales, and sea birds have provided the Eskimos with skins and oil, meat and sinew, and with the inspiration for hauntingly beautiful legends, powerful dances, and traditional ivory carvings. But the Diomederers no longer subsist, as they once did, solely on the marine plants and animals of their islands and of the Bering and Chukchi seas. Twentieth-century technology has transformed their way of life and their relation to the natural world.

Contact with the outside world came when Russian and English explorers penetrated the northern seas in the 1700s. In the nineteenth century, Yankee whalers pushed north in quest of bowhead whales. The whaling ships sailed into the northern Bering Sea in late April to early May. Waiting for the ice to recede northward so they could pursue the bowheads into the Beaufort and Chukchi seas, the whalers traded with the natives for hunting implements, skin clothing, furs, and raw and carved ivory. This contact spurred a desire among the Eskimos for goods that were novel and delightful but always expensive. Coffee, tea, and sugar became as much staples for the Eskimos as they were for the whalers.

The coastal Eskimos could trade a wide variety of items, including baleen, fur, fish, ivory, and jade. The Diomederers, however, had mainly ivory. For centuries the strategic location of their island prompted these people to carve and trade, initially, for fish and furs from the mainland, then for glass beads and Asian trade goods via Siberia. Finally, the tempting novelties of the Yankee whalers were added to the flourishing trade.

The Diomederers became specialists at carving exquisite bracelets of ivory and baleen, lifelike walrus images, and representations of other animals and spirits that shaped their culture. Carving evolved over the decades. Ivory tusks drilled and etched into cribbage boards and such trinkets as swizzle sticks, gherkin forks, napkin rings, and statuettes of copulating polar bears joined the more traditional carvings of whales, walruses, and seals. Ivory became the basis of the Diomederers' economy.

Fred Bruemmer

In recent years the soaring inflation that has swept the lower forty-eight states has reached the Eskimo villages of Alaska, spurring an even greater effort among the Diomeders to acquire ivory. The cost of living in rural Alaska is exorbitant, but it pales beside the prices Diomeders must pay for what have become necessities of life. During the spring of 1979 gasoline cost $154 for a 55-gallon drum; by midsummer it rose to $206 a drum or $3.75 a gallon. Butter now sells for $2.55 per pound, and five pounds of sugar cost $2.90.

Diomede's high prices are largely the result of its inaccessability—it lies across twenty-four inhospitable miles of ocean from mainland Alaska. Groceries and mail arrive by skin boat during the summer. During the winter months supplies are brought by planes that land on the sea ice in front of the village, but these deliveries are at the mercy of capricious winds and shifting ice.

The remoteness of the island was poignantly impressed upon me one evening as we were hunting. A friend from Anchorage had joined our crew. He urged John to accompany him on a fall moose hunt in interior Alaska.

"When will this be?" John asked.

"We'll go in October," answered Joe.

Shaking his head, John sighed, "No, I have to be home in October. Otherwise I might not get in for the winter."

The brutally high cost of living has forced the Eskimos to rely heavily upon their one marketable commodity—ivory. On Little Diomede the yearly harvest of walrus has long since surpassed the number required to supply the meat needs of the village. After each spring's initial hunting trips, very little meat is retrieved from the animals killed. Other villages, such as Savoonga and Gambell on Saint Lawrence Island, have been slower to change, but now they too are turning inexorably toward increased walrus hunting for ivory rather than for food. The two ivory tusks carried by both male and female walruses, and the penis bone (baculum) of the male are retrieved, but the carcass is abandoned on the ice or pushed into the sea. Ivory carvings find a ready market in Nome or Anchorage. The art can be a profitable one. A young man from Diomede told me he could make $260 a day carving ivory, more if he really worked at it.

Hunting as a means of providing an income from ivory has touched off a blazing controversy in Alaska, one that has drawn national and international attention. Headless walrus carcasses washing up on Russian shores have placed Americans in an embarrassing light. The Soviet Union also harvests walrus annually, but the hunt is carried out under strict regulations and in a nonwasteful manner.

The killing of walrus for ivory alone stirs passionate emotions outside the Eskimo community, as well as within. The natives commonly either refuse to admit the practice exists or claim vehemently that this is bonafide subsistence. "We have hunted walrus for thousands of years," an elderly Eskimo recounted. "They have provided us with what we needed in the past, and they provide us with what we need now." What they need now, however, includes snowmobiles, television sets, slide viewers, generators, and outboard motors.

The softly spoken words of an old Eskimo emphasized the changes that have come to the villages. "When I was young," he said, "the village was quiet all the time and the whales and walrus would come very close to shore." He turned from the sea and glanced disdainfully at the roaring village generators. "Now we have snowmobiles, generators, six-wheelers . . . too much noise. The game never comes close anymore."

The changes are indeed great. Although skin boats are used by Diomeders and occasionally in the other villages, aluminum skiffs with powerful outboards have become the preferred craft. (The skiffs are faster than the skin boats, but they are more vulnerable to the crushing ice pack.) High-powered rifles have long since replaced the ivory lances and harpoons of earlier years. CB radios, binoculars, and compasses are acquisitions that have turned the Eskimo into a more effective hunter.

Yankee whalers certainly set a miserable example of restraint. When bowhead stocks declined in the 1870s, the whalers took walrus by the thousands. The ivory was chopped from the skull and the blubber rendered down for the valuable oil. In a ten-year period 100,000 walruses may have been harvested by whaling crews.

This intensive hunting sent the walrus population into a dramatic decline, from an estimated 200,000 animals to a low of 50,000 in the 1940s. The walrus herds were so decimated that it became uneconomical to hunt them and the industry died. Commercial walrus hunting was officially closed in 1941 with the passage of the Walrus Act, which prohibited the export of raw ivory from Alaska. The walrus population began to increase in the 1950s and today the herds in the Bering and Chukchi seas number between 140,000 and 200,000 animals. Walrus are "hauling out," or resting on shores and islands where they have not been seen for decades, indicating a rising population. Now the contention that the walrus population is dangerously high is voiced loudly and unanimously in most villages.

With the passage in December 1972 of the Marine Mammal Protection Act, the federal government took over marine mammal control from the state of Alaska. All hunting of marine mammals was abruptly stopped, bringing to an end the sport hunting of walrus allowed by the state. Eskimos, Indians, and Aleuts, however, were granted an exemption that allowed them to harvest these animals for subsistence purposes or for the creation of authentic articles of native handicraft. In January 1973, Alaska petitioned for re-

turn of the management of nine species of marine mammals important to coastal residents, both Eskimos and nonnatives. In April 1976 the federal government hesitantly yielded jurisdiction only over walrus, mandating that the annual harvest must not exceed 3,000 animals. If this number was exceeded, control of walrus hunting would revert to the federal government.

When the state of Alaska resumed management of walrus in 1976 it accepted a volatile situation. The number of animals killed in the spring hunt began to rise as more and more walrus were taken for their ivory. According to the Alaska Department of Fish and Game, Alaskan Eskimos took roughly 1,600 walrus in 1962; 2,300 in 1974; 2,600 in 1975; and nearly 3,000 in 1976.

As the number of walrus harvested approached the federal ceiling of 3,000, a limit was imposed and village quotas were set. Past dependence upon walrus was considered, as well as the availability of wage-earning jobs to meet the cash needs of the Eskimos. The villages of Gambell, Savoonga, and Little Diomede—historically the most dependent upon walrus—were initially accorded 450 walrus per year. The quota system was poorly received, difficult to enforce, and unpopular with both natives and those state representatives working in the villages. Hunting limits imposed by those who had ruthlessly depleted their seas of whales and walruses seemed ludicrous and high-handed to the Eskimos.

"You don't know what it is to be Eskimo," claimed one young man. "Out here hunting is our way of life. Carving ivory is our livelihood. We don't want welfare supporting us and we don't want to be forced from the villages.

"There are too many walrus now," he continued. "The Eskimos know this. There is no reason for these quotas. You do not understand how we live."

A biologist who has spent much time with the Eskimo people and is liked by them had this to say: "People speak of the noble, ideal Eskimo who wastes nothing. Unfortunately, that concept is fictitious, just as is the other voiced extreme that would have them all unscrupulous renegades. The truth lies in the middle. They are a people and a culture worthy of respect, but they are being bludgeoned by change. They are reacting as any of us would, taking each step in response to what they have and what they can do. Some are tougher than others. They hold up under the pressure while others break."

The swiftness with which changes have come to the Eskimos has generated problems long associated with the acculturation of one society into another. The Eskimos are not consciously turning from traditional ways. They are responding naturally to the choices offered them. The new variety of foods found in the stores is appealing, snowmobiles are faster and easier to handle than dog teams, and winter clothes and hunting gear are more readily bought than made in the painstakingly traditional fashion. Yet these changes are eroding traditions that have been a source of dignity and pride to the Eskimos.

In the past the Eskimos had no alternatives to facing the rigors of the Arctic environment. Hunting was a daily necessity that provided the Eskimo culture with a powerful, unifying theme. Legends portraying hunters and dances depicting courageous sea journeys were inspiring and supportive, fostering strong village ties. But modern technology and an ivory-based economy (which wastes valuable animal protein) have introduced competition among the hunters. Moreover, there are now alternatives to hunting. The Arctic continues to be a rugged home, however, and without the constant endeavor of hunting, the long winters can weigh heavily. Intriguing new life styles, conveyed vividly by weekly movies and taped television programs, impart a restlessness and dissatisfaction to the younger Eskimos. The legends and dances are still there, but their influence is weakening, yielding to that of bingo and basketball.

Rick Furness; Alaska Photo

The walrus hide that is being split may be used to build an umiak, or skin boat, which is still used on Little Diomede Island.

Unfortunately, some of the social transitions affecting the villages are more serious. Although most communities have voted themselves dry, liquor is easily obtained, and alcoholism, with all its associated problems, is a prevalent disease. Drug abuse is making inroads in the tiniest, most remote communities. Last year a youth died of an overdose of angel dust in the isolated village of Scammon Bay, north of the Kuskokwim River on Alaska's coast. The suicide rate is overwhelmingly high, a tragic index of the depression plaguing the Eskimos, especially the younger individuals.

John Iyapana was the captain of the crew I joined. Although the hunts were ofen long and arduous, John enlivened them with stories of past hunts and adventures. He and the others in the crew pointed out rocks and landmarks on the Russian and American mainlands, giving their Eskimo names and indicating where it was wise to watch for changing weather. Late one afternoon we were hunting close to Little Diomede. We had not seen any walrus or seal and decided to run in against the island and have *yo kuk* ("coffee break"). As we lay on the rocks waiting for the water to boil, John raised his hand toward the cliffs above us and said, "The old people say this is the best place on the island for boot liners. Come on, I'll show you how to gather the grass." We climbed the hillside and filled a large bag with the soft, dry grass.

"Bend this gently in a figure eight, without breaking it," John explained. "Then lay it on the bottom of your mukluks [skin boots]." He smiled, "It's warmer and softer than any wool sock."

The camaraderie and rapport between myself and the Eskimos was only occasionally subdued by reference to hunting walrus for their ivory. The hunters are somewhat defensive

SCIENCE

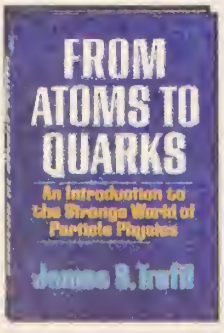
51 books to choose from on these 4 pages.

BOOKS THAT ANSWER

Q: Are modern computers as smart as any living animal?

A: Today we have machines with the intelligence of the earwig, a tiny insect. This may not seem much, until you realize it took evolution millions of centuries to make the same leap. (See *The Micro Millennium.*)

Q: Can time speed up and slow down?



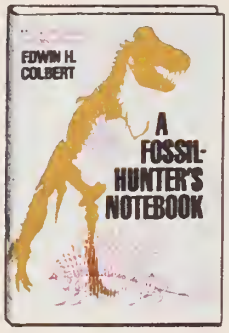
A: Yes, by the theory of relativity. Consider two twins. One leaves Earth in a spaceship, travels close to the speed of light, and returns. Although he's only a few weeks older he's astonished to find that Earth has aged hundreds of years. His twin brother, and everyone he knew, is long since gone. (See *Einstein's Universe.*)

Q: Most important brain functions are represented in both the right and left halves. But which vital function is only found on one side?

A: Speech. There are three speech areas in the brain, but in the vast majority of people they are all on the left side. (See *The Origin of Consciousness in the Breakdown of the Bicameral Mind.*)

Q: What seemingly unrelated invention was one of the main causes of the separation of classes in the Middle Ages?

A: The chimney. Before its invention, people of all classes had to mingle in the same room around an open fire. The chimney enabled heat to be distributed to different rooms, encouraging class separation. (See *Connections.*)



135 From Atoms to Quarks: An Introduction to the Strange World of Particle Physics. James S. Trefil. (Pub price $12.95)

123 Lucy: The Beginnings of Humankind. Donald Johanson and Maitland Edey. (Pub price $16.95)

121 The Complete Medical Guide (4th Edition). Benjamin F. Miller, M.D. Revised and updated by Lawrence Galton. (Pub price $19.95)

158 Time Warps. John Gribbin A fascinating discussion of time—its history in human thought, current scientific knowledge and the possibilities of such things as time travel, parallel universes and reincarnation. (Pub price $13.95)

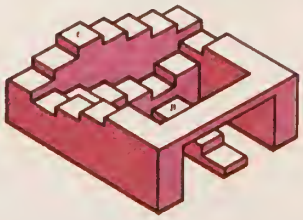
132 A Fossil-Hunter's Notebook: My Life with Dinosaurs and Other Friends. Edwin H. Colbert. (Pub price $15.95)

116 Dolphins, Whales and Porpoises: An Encyclopedia of Sea Mammals. David J. Coffey (Pub price $17.95)

109 A Golden Thread: 2500 Years of Solar Architecture and Technology. Ken Butti and John Perlin. (Pub price $15.95)

131 Hans Bethe: Prophet of Energy. Jeremy Bernstein. (Pub price $12.95)

153 Wildlife of the Deserts Frederic H. Wagner (Pub price $18.95)



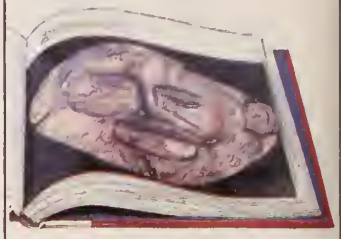
117 Prehistoric Avebury Aubrey Burl. Striking photographs and a fascinating text explore the mysteries and magic of "the most spectacular prehistoric monument in the British Isles." (Pub price $19.95)

106 Without Me You're Nothing: The Essential Guide to Home Computers. Frank Herbert with Max Barnard. (Pub price $12.95)

114 Unfinished Business: Pressure Points in the Lives of Women. Maggie Scarf. (Pub price $14.95)

110 The Lives of a Cell: Notes of a Biology Watcher. Lewis Thomas. (Pub price $8.95)

139 Connections. James Burke *Softcover.* (Pub price $10.95)



111 Mathematical Circus Martin Gardner. (Pub price $9.95)

100 Einstein's Universe. Nigel Calder. A fascinating and lucid explanation of the theories that changed man's understanding of time, space and motion. (Pub price $10)

128 The Micro Millennium Christopher Evans. A fascinating analysis of the computer revolution and the dramatic impact it will have on our lives. (Pub price $10.95)

125 Maps of the Mind. Charles Hampden-Turner. (Pub price $14.95)

157 Notebooks: B. F. Skinner. Edited and with an Introduction by Robert Epstein (Pub price $15.95)

101 Mysteries of the Past. Lionel Casson, Robert Claiborne, Brian Fagan and Walter Karp Editor: Joseph J. Thorndike, Jr. (Pub price $34.95)

124 The Origin of Consciousness in the Breakdown of the Bicameral Mind. Julian Jaynes (Pub price $12.95)

129 The Illustrated Origin of Species. Charles Darwin. Abridged and Introduced by Richard E. Leakey. (Pub price $25)

WONDERFUL QUESTIONS.

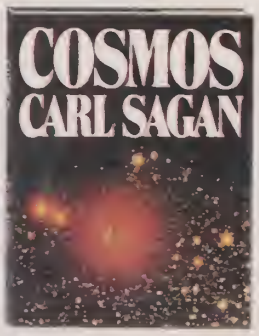
Painting by Don Dixon © Don Dixon

149 Science and the Supernatural. John Taylor
A distinguished physicist investigates psychic healing, telepathy, psychokinesis and other paranormal phenomena.
(Pub price $10.95)

134 Mathematics: The Loss of Certainty. Morris Kline
(Pub price $19.95)

144 The Gnostic Gospels
Elaine Pagels. (Pub price $10)

140 Earthly Pleasures: Tales from a Biologist's Garden.
Roger Swain. (Pub price $10)



133 John Von Neumann and Norbert Weiner: From Mathematics to the Technologies of Life and Death. Steve J. Heims. A look at the careers of two of the 20th century's most extraordinary scientists. (Pub price $19.95)

126 Broca's Brain: Reflections on the Romance of Science.
Carl Sagan. (Pub price $12.95)

118 A Matter of Life: The Story of a Medical Breakthrough. Robert Edwards and Patrick Steptoe. The extraordinary behind-the-scenes story of the first baby conceived outside its mother's womb.
(Pub price $9.95)

© Giorgio Gulaco/ Bruce Coleman, Inc

103 Cosmos. Carl Sagan.
(Pub price $19.95)

113 The Arbor House Treasury of Modern Science Fiction
Compiled by Robert Silverberg and Martin H. Greenberg
(Pub price $19.95)

112 Favorite Audubon Birds of America. Introduction and Commentaries by Roger Tory Peterson. (Pub price $17.95)

142 The Expanding Circle: Ethics and Sociobiology. Peter Singer. A remarkable effort to synthesize the insights of both science and philosophy on the origins of ethics.
(Pub price $10.95)

Quasars at the edge of the universe, pouring out awesome amounts of energy.

Black holes twisting space and time like a pretzel—and gobbling down whole planets.

Here on Earth, the stunning adaptability of life: a desert animal that *swims* through sand the way an eel swims through water. And the ingeniousness of man: a new concept that may enable us to generate limitless electricity by duplicating the process that powers the sun.

And, in each of your cells—a substance called DNA, compressing into an invisibly tiny volume all the information needed to create *you*.

As someone living in an age of unparalleled discovery, you've undoubtedly been curious about things like these.

And you've probably noticed the explosion lately in books about science for people who are not scientists.

But how do you know which are the best? And where do you find them?

Let a whole new kind of book club do it for you. Book-of-the-Month Club/SCIENCE. A division of Book-of-the-Month Club.

If you've ever wanted the chance to really explore the wonders of modern science, this is the way. Because now you can be sure you're getting works that are understandable, lively and authoritative.

Book-of-the-Month Club/SCIENCE will lead you to books that indulge your sense of wonder to the fullest, sparkle with discovery, tantalize with new questions.

Books that can change your way of thinking. And the way you and your children live.

Here are books that will take you to the belly of a distant star. To the inside of an atom. To the love song of a bird.

Books that explore the greatest wonder of all—the human mind that is able to wonder.

It's all here. The vast worlds within you, around you, beyond you. The magic of the commonplace and realms where the commonplace is almost indescribably exotic. All joined together in a fine book club that identifies—and makes available to you—the best books about science. The science books *you* want to read.

We invite you to start by taking any 3 for $2 each.

WHERE THE WONDER IS

Prices shown are publishers' U.S. prices. Outside the U.S., prices are generally somewhat higher.

about this activity, an attitude prevalent throughout the villages. It envelops the entire issue in a smothering shame that only serves to make more difficult the search for solutions. The hunting of walrus solely for ivory is an understandable, albeit lamentable, result of an expanding ivory market. If the guilt were to be lifted from the Eskimos, perhaps by a realization that their position has been shaped as much by our culture as by theirs, the managing agency and natives could work together more harmoniously.

Which agency will manage the walrus harvest is going to be a puzzling question. The state of Alaska returned control of walrus to the federal government on July 1, 1979. The federal restrictions placed upon state management were felt to be untenable and cumbersome by the state biologists involved. Just prior to this action the Alaska State Board of Game rescinded the walrus quotas, acknowledging that the walrus herds may be undergoing population stress. On a biological basis, then, the state gave tacit approval for an increased harvest of animals.

Under federal control the Eskimos are again being allowed unlimited subsistence hunting. Walrus will no longer be subjected to sport hunting by nonnatives, which the state had allowed shortly after it resumed management in 1976. The number of walrus harvested by sport hunters in 1976 was about 150 out of the yearly take of 3,000. The Eskimos are divided over the issue of sport hunting because guiding associated with these hunts brought substantial money into the Eskimo community.

Management by the federal government creates an additional dilemma. Under the Marine Mammal Protection Act the native exemption is granted for subsistence and handicraft use only. The state recognized that walrus hunting is closer to a commercial endeavor and was seeking markets for the surplus products. Walrus meat is strong and rich but quite palatable. Certainly in a world starving for protein this meat could be utilized. The thick hides of the bull walrus, although heavy, cumbersome, and difficult to retrieve, are used in industry on buffering wheels. Walrus stomachs can be scraped, dried, and made into the traditional skin drum of the Eskimos. This spring, coastal villages were buying prepared stomachs for $75 a piece from the Diomede hunters. This search for commercial outlets may be impeded, depending upon the most recent interpretation of the Marine Mammal Protection Act. Although the wording of the act is vague regarding what constitutes waste of an animal, the native exemption is obviously aimed at subsistence use and not commercial enterprise. Programs such as the installation of large community freezers in some villages to hold excess walrus meat are suddenly left on unsteady ground. Although these freezers would hold additional meat for the Eskimos' use, they are meant primarily to facilitate the commercial sale of walrus meat. Restaurants in Nome and Anchorage have expressed interest, and the Japanese have made inquiries.

Chris Arend Alaska Photo

Diomeder carvers find a ready market for walrus-ivory figures, such as this puffin. The income from such carvings is supplemented by the sale of ivory swizzle sticks and pickle forks to mainland tourists.

It is difficult to foresee what walrus management will be like under the federal government. If the present Eskimo hunting practices are interpreted as wasteful, a herculean effort will be required to curtail their harvest. The ivory trade could be outlawed, but a flourishing black market already exists, as evidenced by the illegal traffic in polar bear skins traced to Alaskan Eskimo villages. And the Eskimos would not be easily dissuaded from hunting. They feel no one has the right to take that from them. Biological evidence further complicates the picture: The walrus population may be at a level where it could absorb the Eskimos' harvest without serious impact.

In the clear light of an Arctic evening I watched a drama unfold on the ice, one that summed up the complexity and intricacy of implementing effective walrus management. Our crew had fired into a walrus pod. Most of the animals plunged into the sea, leaving behind three dead companions and a young, wounded bull, with tusks protruding a scant six inches, which struggled valiantly to reach the water. Normally, hunters quickly dispatch a wounded walrus, and I looked at our crew, expecting a rapid reaction to the bull left alive on the ice. But no one moved.

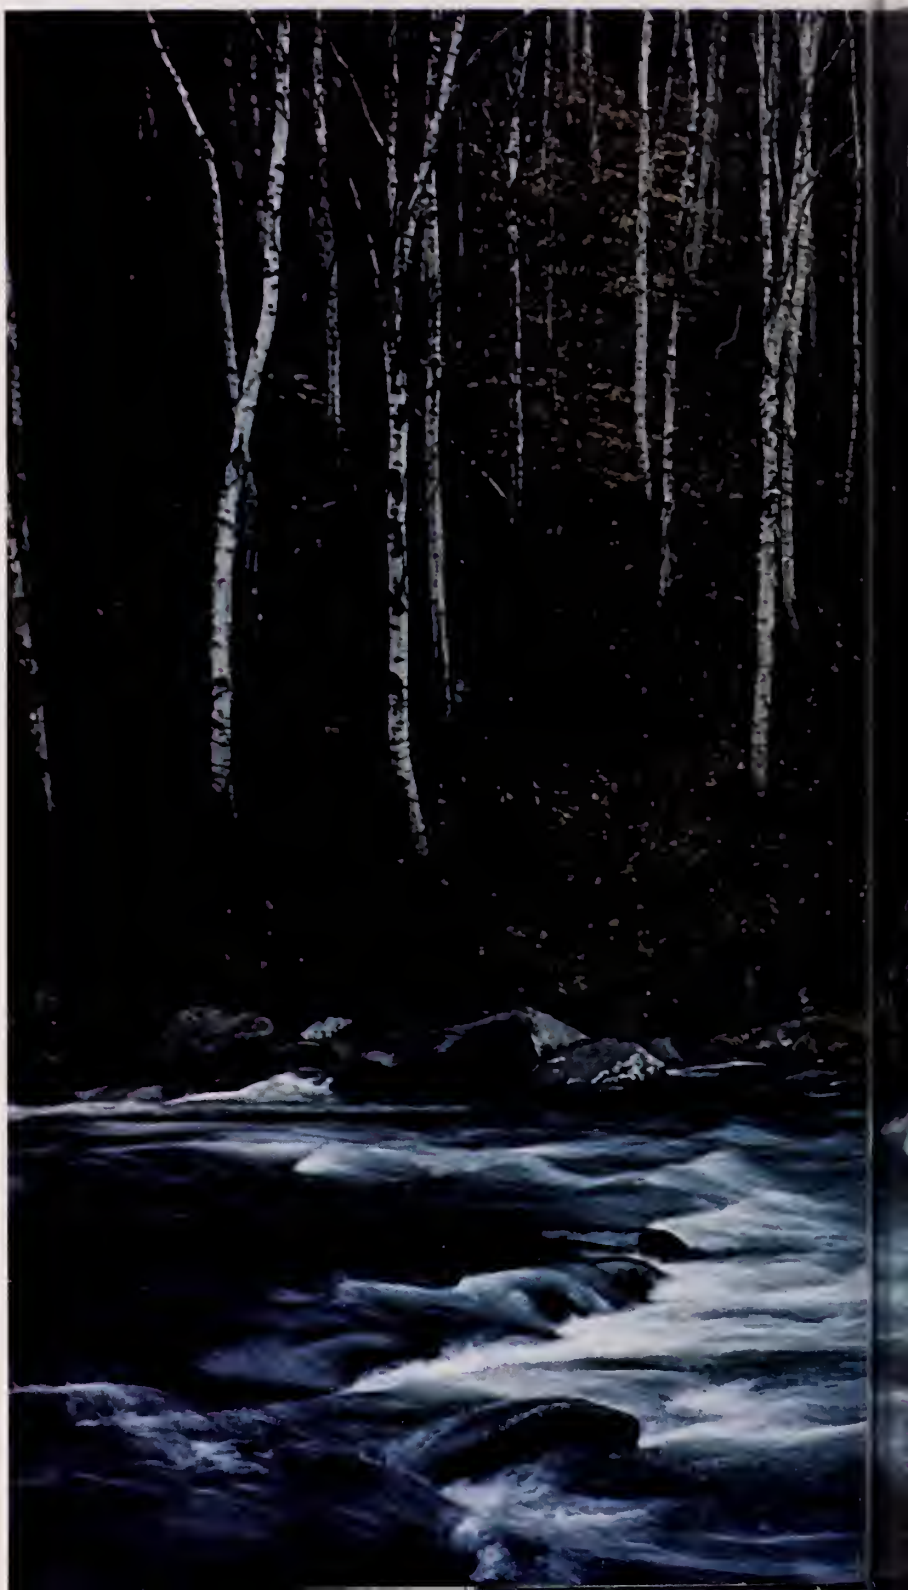
As the Eskimos continued to watch the walrus intently, I realized that they were hoping the animal would reach the water. If it was not retrieved, the walrus would not be included in the village quota.

I looked back to the young walrus and thought sadly what a strange ritual was being performed. Because limits had been imposed on the number of animals harvested, this walrus might have been wasted simply because his ivory was small. And the hunters, a people who have lived from the animals of the sea for centuries, have been placed in a situation where they permit this to happen.

The walrus writhed a few more times. At last, one of the hunters raised his rifle and fired. The animal lay still. We moved in to butcher the carcasses, an embarrassed quietness pervading the air. It was an impressive example of well-intentioned regulations having unforeseen effects when actually applied.

When the cold winds begin to sweep down from the Beaufort and Chukchi seas this fall, the walrus herds will funnel through Bering Strait and move into their wintering grounds farther south. Spring will come again to the Bering Sea Eskimo villages, and with it, the walrus hunting that is so much a part of these people and their lives. Progress can be made toward a more efficient harvest, but the steps toward that end should be carefully weighed and closely scrutinized. The Eskimo way of life, whether it be called traditional or twentieth-century mainstream, is at stake. □

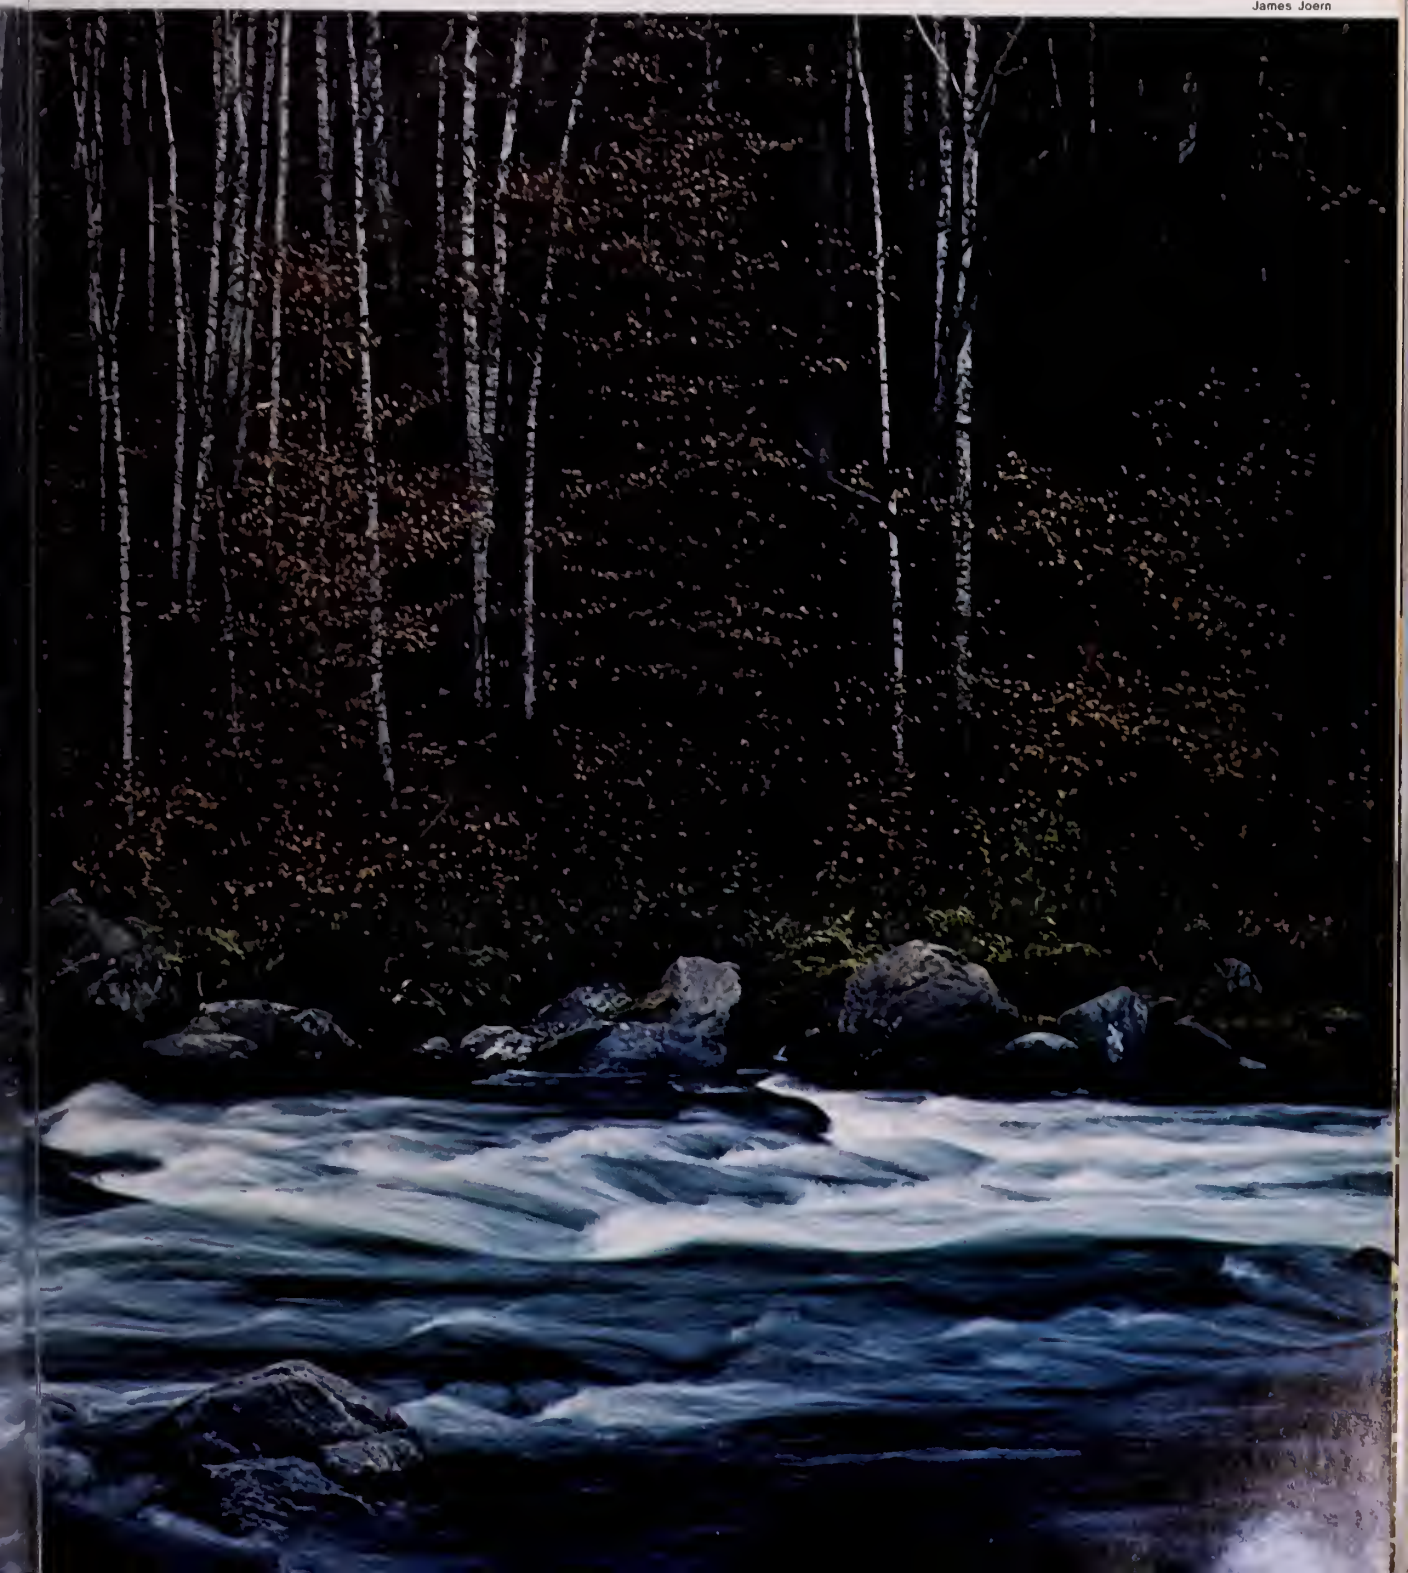
Acid Rain and Gray Snow



In many parts of the world, rain is no longer gentle and snow no longer white

by George R. Hendrey

Mountain lakes and streams, long regarded as symbols of purity, are becoming increasingly contaminated by atmospheric pollution. Rain and snow that have become loaded with toxic chemicals, mainly acids, have been falling over nearly all of the eastern United States, southeastern Canada, northern Europe, and southern Scandinavia. More recently, California, Colorado, and Washington State have been added to the list of regions known to be receiving acidic precipitation. In many places, the rain is so polluted that numerous species of freshwater animals would be killed if they were exposed directly to water having its average chemistry.



The pollution is caused primarily by the combustion of large amounts of fossil fuels—coal, oil, and gas. Oxides of sulfur and nitrogen created in the combustion process are released into the atmosphere, where they react with oxygen, water, and other substances in the air to form sulfuric acid and nitric acid. These two pollutants are what cause the rain to be so acidic.

In 1940, about 22 million tons of sulfur oxides and about 6.7 million tons of nitrogen oxides were spewed into the atmosphere from American homes, factories, and power plants. By 1976 these emissions had risen to 32 million tons of sulfur oxides, a 45 percent increase, and 25 million tons of nitrogen oxides, a 273 percent increase. Large increases in power plant emissions of sulfur oxides during this period were partly offset by decreased

Streams in certain mountainous areas, including the Adirondacks, are particularly sensitive to acidification. The drainage basins of such streams typically have relatively little soil cover and a minimum of minerals capable of neutralizing the acidity of precipitation.

James Joern

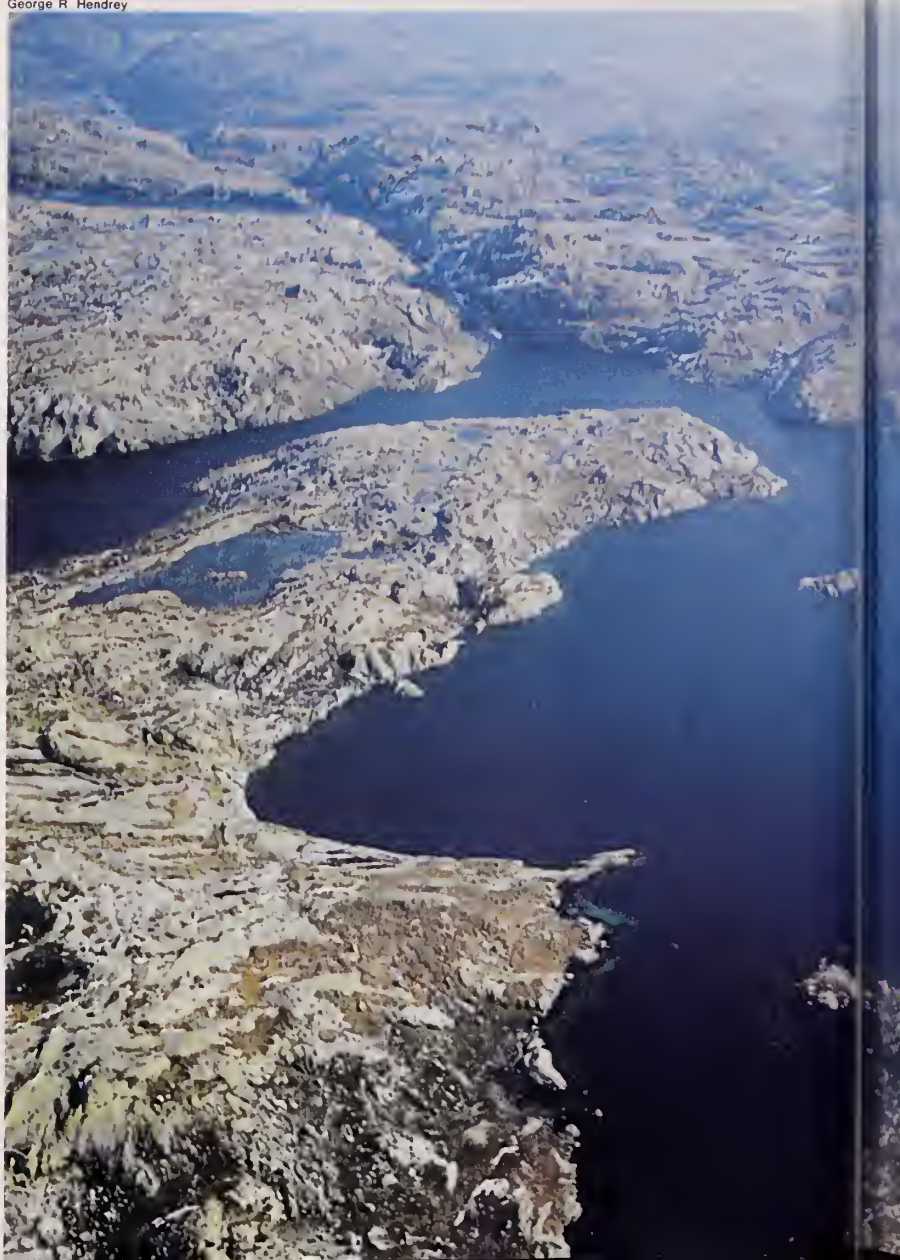
emissions from other industries and from homes and businesses that shifted from coal to oil or gas. The total amount of sulfur oxides released into the atmosphere therefore did not increase as dramatically as the amount of nitrogen oxides. The increased nitrogen oxide emissions were primarily from motor vehicles, factories, and power plants, in that order.

Ironically, the installation during this time of extremely tall smokestacks at some power plants often helped to transform a local problem into a regional one. The tall stacks emit large amounts of pollutants high into the air where they are carried long distances by the wind, thereby gaining more time in which to react chemically to form sulfuric and nitric acids.

There is little evidence so far that airborne acidity has injured crops and forests, but the evidence of environmental damage in freshwater lakes and streams in severely affected regions is unmistakable. Some lakes are more susceptible to acid precipitation than others. Among the factors that determine the extent to which a lake may become acidified are the amounts of acid or acid-forming materials that are deposited, the sensitivity of the soil and bedrock to acidification, and the topography of the watershed.

When scientists speak of a lake being acid, they are referring specifically to the concentration of ionized hydrogen in the water. In chemical shorthand, this form of hydrogen is specified as H^+. The presence of H^+ is what gives solutions their acidity.

For the sake of convenience, the concentration of H^+ is often expressed in terms of the pH scale. The scale is logarithmic, so that a rise or fall of one pH unit represents a tenfold change. Thus, pH6 is ten times more acidic than pH7, and pH5 is a hundred times more acidic than pH7. In unpolluted, clear, natural waters, the pH level is rarely below 6.



In neutral water (with a pH of 7), the H^+ concentration is very low, about one-tenth part of H^+ to a billion parts of water, or 0.1 parts per billion (ppb). Pure water, which is in equilibrium with the atmosphere, will have carbon dioxide dissolved in it, making a slightly acidic solution of pH5.6, or 2.5 ppb. This is often referred to as the pH of "unpolluted" rain. Many lakes that have been acidified by acid rain now have concentrations of 30 parts of H^+ per billion parts of water—300 times the concentration of acid in neutral water. We know that the concentration of H^+ in rain in the northeastern United States is sometimes as high as 3,000 ppb, which is 30,000 times as high as neutral water and more than 1,000 times more acidic than "unpolluted" rain.

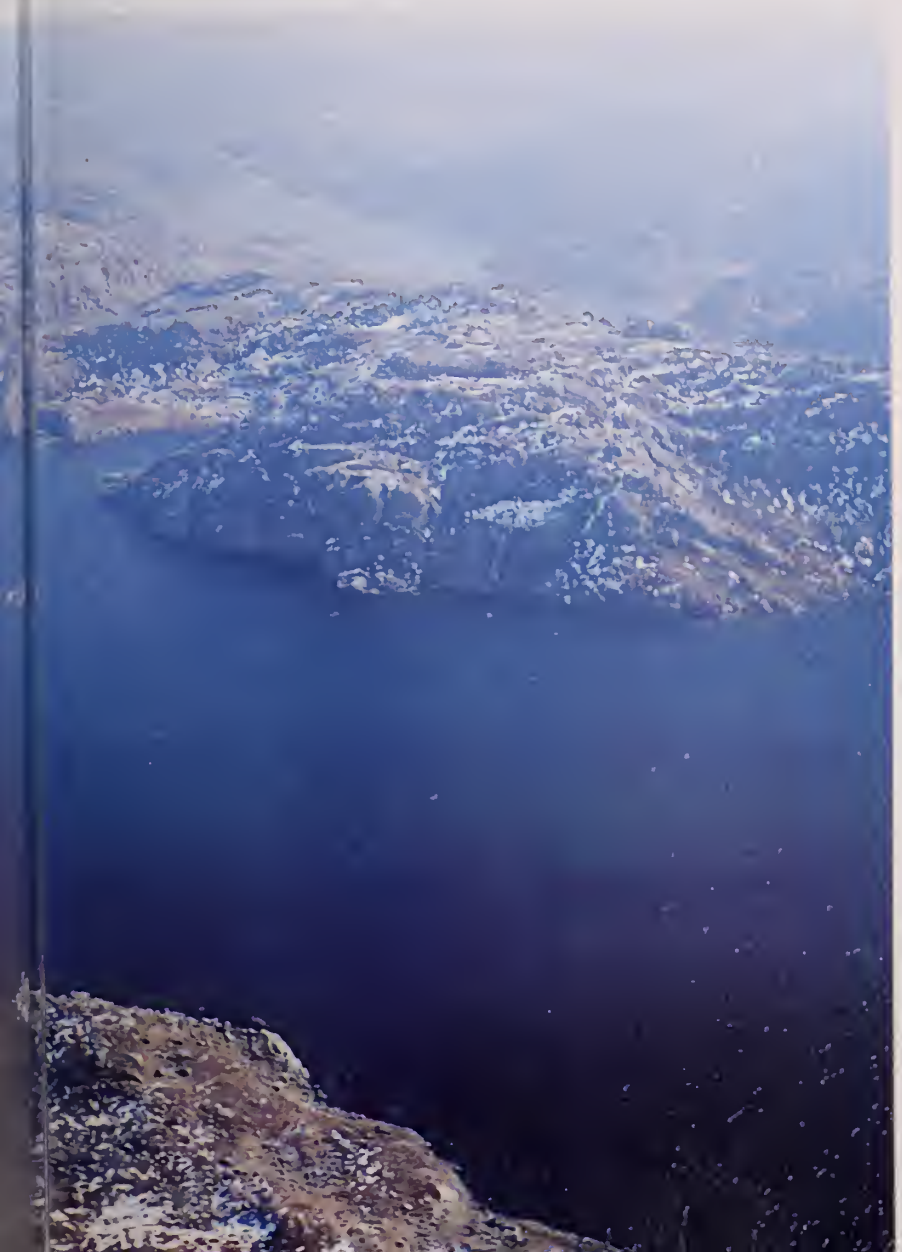
The ability of water to neutralize H^+ is called its buffer capacity, and it is determined, for the most part, by the alkalinity of the water. Alkalinity, in turn, comes primarily from the weathering of minerals in the watershed. Limestone and other, similar minerals are the most important substances that provide alkalinity and, hence, buffering capacity.

As acidification proceeds, the alkalinity is removed in the form of carbon dioxide and lost from the water. This diminishes the water's acid-neutralizing capacity. When acids deposited from the atmosphere percolate through a watershed, aluminum is also dissolved from soil and rocks. Hydrogen ions are exchanged for aluminum ions in the minerals of soil and rocks. By decreasing the amount of H^+, this process may decrease acidity, but aluminum can be a threat to fish. Aluminum concentrations, which are usually well below 0.1 parts per million (ppm) in lakes and streams, are greatly elevated through the exchange of H^+ in regions with very acidic precipitation. Acidified waters in the Adirondacks, for example, have concentrations of 0.2 to 1 ppm of aluminum. At 0.2 ppm, aluminum is quite toxic to fish.

Most of the regions in which lakes and streams are acidified have thin soils and relatively large amounts of

George R. Hendrey

exposed bedrock. In these areas the chemical characteristics of the bedrock determine the fate of the acids deposited from the atmosphere. Limestone terrain has a nearly infinite ability to buffer H^+, but hard crystalline rocks such as granites contain no minerals that could contribute alkalinity, are slow to dissolve, and therefore have little ability to neutralize acids.



The freshwater regions of North America where acidification is most severe are the Canadian Shield and the Adirondack Massif. In less sensitive regions the bedrock is more extensively covered by soil, derived either from the local bedrock by means of erosion or transported into the area by water, winds, glaciers, or landslides. A transported soil, in contrast to local soil, may be quite different from the bedrock under it, and deep soils as well as shallow ones can be transported. Nevertheless, whatever the source, the deeper the soil, the greater the possibility of contact with water passing through it. Therefore, even soils with little buffering capacity can, if they are deep enough, neutralize acidic precipitation.

The topography of a region has an important influence on the susceptibility of its lakes and streams to acidification. Mountainous areas, for instance, are likely to have shallower soils and more exposed bedrock than lowlands. Many mountain streams have little water and sometimes dry up. Close to the top of their watershed, these streams get relatively little ground water and, since they swell rapidly during small rainstorms, are in many cases vulnerable to the chemical effects of rain. Studies conducted last year in the Shenandoah National Forest by James Galloway of the University of Virginia show this to be true for some streams in the Blue Ridge Mountains of the southeastern United States. Before these studies, this region was not known to have been affected by acidic precipitation.

Another way in which topography influences lake and stream acidification is by increasing the amount of precipitation they receive. When bodies of air moving across lowlands encounter a mountainous region they are forced to rise. As they rise, they encounter diminishing atmospheric pressures, and the air expands to occupy a larger volume with the same mass. The heat contained in the rising air parcel is also distributed throughout a larger volume, so that the temperature of the air decreases. This cooling process is what causes clouds to form and rain to fall more frequently over the mountains than over lowlands. The first rain that falls after a body of cooled air has passed through a mountainous region tends to remove more pollutants than subsequent rainfalls do, thereby causing the mountains nearest the source of the acidic air pollution to receive more acid than neighboring areas.

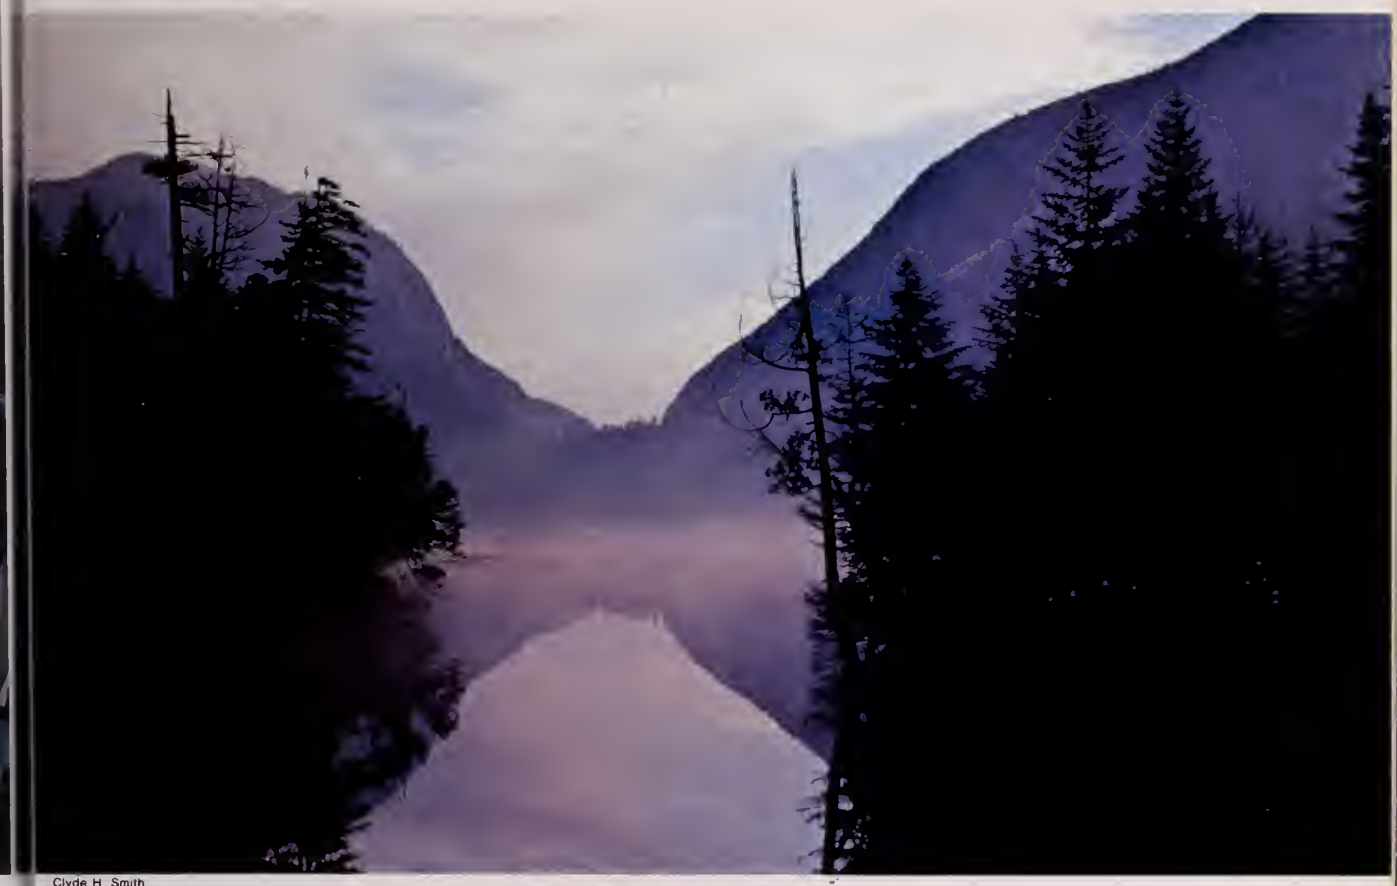
In 1979 a computerized inventory of water chemistry data from the eastern United States was set up at Brookhaven National Laboratory on Long Island. Known by the acronym ACID (for Acidification Chemistry Information Database), this inventory reveals that waters with low alkalinities (that is, less than 100 ppb) are found in many areas of the eastern United States. A large number of such headwater streams have probably become at least temporarily acidified by rain or snow that is strongly acidic.

Abundant snow is a feature common to the geographical regions most heavily affected by acidification. But much of the snow is no longer pure. Like the rain, it carries a burden of pollutants released by humans into the atmosphere. In fact, falling snow is

The lakes and streams of southern Norway began to lose their fish populations decades ago. There are now thousands of lakes in this region from which fish have been completely eliminated.

Lenny Newman, Brookhaven National Laboratory

The installation of tall smokestacks at power plants, beginning in the 1950s, allowed emitted sulfur oxides to spread more widely before being deposited, providing time for greater portions to be converted into sulfuric acid. Such airborne acid can fall as acid rain hundreds of miles from the source of pollution.



sometimes a dirty gray. And not just in industrial towns, but in areas such as south-central Norway, many hundreds of miles from the sources of the pollutants. Snow cores taken from that region of Norway contain gray bands corresponding to specific snowstorms that carried fly ash and other contaminants east and northward from the industrial regions of Great Britain and the rest of Europe. I have not yet seen this kind of banding in the snows of the Adirondack Mountains, probably because of the relatively stringent rules concerning airborne emissions of particulate pollutants in the United States. Some American snow, however, like the snow in Norway, is contaminated with acids.

When rainwater freezes to form sleet, the ice crystals created in the process tend to exclude molecules of all substances other than water. A water droplet containing sulfuric acid will thus become a small clump of ice covered with the droplet's total amount of acid. The acid on the outside of the tiny clump is accordingly in a more concentrated form. Furthermore, ice and snow crystals serve as attachment sites for sulfur and nitrogen oxides, where the adhering oxides can react with other pollutants and water. When the sleet or snow falls to the ground, the pollutants stay bound to the outside of the crystals. As the snow pack ages, a slight melting and recrystallization take place, increasing the size of the ice particles. Since pollutants continue to be excluded from the crystals, they become even more concentrated on the outside of the ice particles. If the partial melting occurs above a layer of solid ice in the snow pack or on a lake, one or more bands of concentrated pollutants may be formed within the snow pack.

As soon as enough melting takes place to allow water to move freely through the snow, the first meltwater will remove a large portion of all of the soluble pollutants. Researchers at the Norwegian Institute for Water Research have shown that this mechanism typically removes 50 to 80 percent of the pollutants in the first 30 percent of the meltwater. The sudden release of acids and other pollutants from snow that has collected for weeks or months can cause drastic acidification in lakes and streams. An example of this process can be found in Panther Lake in the western Adirondack Mountains of New York State. The lake usually has a pH of slightly above 7, almost neutral. But when the snow melted in the spring of 1979, the pH dropped to about 5, an increase in ionized hydrogen of about a hundredfold.

The cause and effect relationship between acid rain and the disappearance of fish was first suggested by a Norwegian fisheries inspector in 1959. It was publicized in Norway in 1966 and has subsequently been well documented. Concern about acid rain was not felt anywhere until Scandinavian scientists began to notice that many lakes and streams in southern Norway and on the west coast of Sweden were losing their populations of fish. The decline in the salmon catch in major rivers of southern Norway is most striking. The Tovdal River salmon catch began an unprecedented decline in the late 1920s. Periodic fish kills, which may have been caused by drops in the springtime levels of pH, possibly combined with simultaneous increases in the concentration of aluminum, gradually reduced the stock of Atlantic salmon in the river (although other factors such as overfishing might also have played a role and cannot be completely disregarded). The scientific documentation for this period is poor, since few pH measurements in streams were made. We do know, however, that in the past two decades the entire Tovdal River, with pH values in the range of 4.6 to 5.2 in 1975, has become so acidic that throughout most of the year Atlantic salmon cannot survive in its waters. These low pH values are in marked contrast to those in Norwegian rivers beyond the reach of airborne acid.

In 1975, Carl Schofield, a fisheries biologist at Cornell University, conducted a survey of 217 Adirondack

Clyde H Smith

Lake Colden in the Adirondacks, once highly prized by trout fisherman, is now so acidic that fish cannot survive in its waters.

lakes at elevations above 2,000 feet. Fifty-one percent of these lakes were found to be acidified to a pH of 5 or less, and 90 percent of those found acidified had no fish. Some of those lakes supported fish forty years ago. Studies made in the 1970s in Canada also show that lakes in certain areas, ranging from southwest Ontario eastward to Nova Scotia, are losing all their species of fish.

Levels of pH and alkalinity taken from the 1930s through the 1950s are now considered unreliable because the methods then used for analysis put chemicals into the water to produce a color indicator of acidity and alkalinity, and that process altered the variables being measured. Electronic methods of measurement have replaced the old techniques, but the unreliability of the old data has caused some people to question whether or not acidification has occurred at all. They suggest that perhaps the lakes were always acidified. The biological data, however, are an independent and reliable indicator of acidification. Fish have disappeared from numerous lakes and streams that are reported, on the basis of measured chemical change, to have become acidified. Fish have also disappeared from hundreds of bodies of waters for which no chemical data from an earlier period are available. These waters are now too acidic and their aluminum concentrations too high for fish to survive. When fish are stocked in such lakes, they die. It's hard to argue with a dead fish.

The futility of stocking such waters is illustrated by the history of Lake Colden, a small lake at an elevation of almost 3,000 feet in the heart of the Adirondack Mountains. Described as a fisherman's paradise, Colden was one of the best trout-fishing lakes in the area but the annual catch declined from the 1950s through the 1960s. Efforts to stock the lake in the 1960s met with failure; the new fish died quickly. The last fish disappeared in 1970.

The food supply available to fish in lakes is greatly altered as acidification proceeds. In those lakes having a pH from 5 to 6—a range in which the ionized hydrogen level has a marginally negative effect on trout—there are significant changes in the availability of different species of zooplankton (microscopic organisms suspended in the water), insects, other aquatic invertebrates, and plants, all of which serve as food for some fish. The number of zooplankton species declines with decreasing pH levels as was demonstrated in my work involving large-scale surveys of Norwegian lakes. Scientists at the University of Bergen, in Norway, evaluated the biomass, or weight, of bottom-dwelling invertebrates in three lakes with a pH range of 4.3 to 4.7 and five lakes with a range of 5.8 to 6.2 and found less food available to fish in the more acidic lakes. Although the availability of fish food organisms has been found to decrease in some acidified lakes, the effects of these changes on fish life have not been investigated.

Some of the invertebrates that are the normal elements of a fish diet have a low tolerance for acid and cannot be found below a pH level of 6. Such is the case with the tadpole

shrimp (*Lepidurus arcticus*). Ordinarily, this organism undergoes a rapid series of molts as it progresses from the egg to maturity. My studies show that a pH of 6, which is only slightly acidic, delays the normal rates of progression through this series of distinct life stages and more and more of the animals die before becoming adult. As the pH level decreases, interference with the progression of life stages and premature death both increase. Another common invertebrate, the freshwater scud gammarus (*Gammarus lacustris*), is also absent from waters with a pH level below 6, and my research has shown that even gammarus adults cannot tolerate a decrease in pH much below the 6 level. Immature stages of this scud would probably be even more sensitive to high acidity.

Animal life of all kinds in lakes and streams, from fish down to the smallest invertebrates, depends upon energy from food, which is derived either from plants growing in the water or from organic litter such as leaves and twigs transported by the wind or the flow of streams. In streams and small lakes or ponds, plant litter is the most important food source for animal life. Ecologists have shown, however, that bacteria and fungi are very important in making these sources of food available to animals, and many invertebrates obtain more energy from eating these microdecomposers than from eating the leaves or other detritus with which the microbes are associated. Decreasing this microbial activity may therefore have profound effects throughout the food web of a stream or lake.

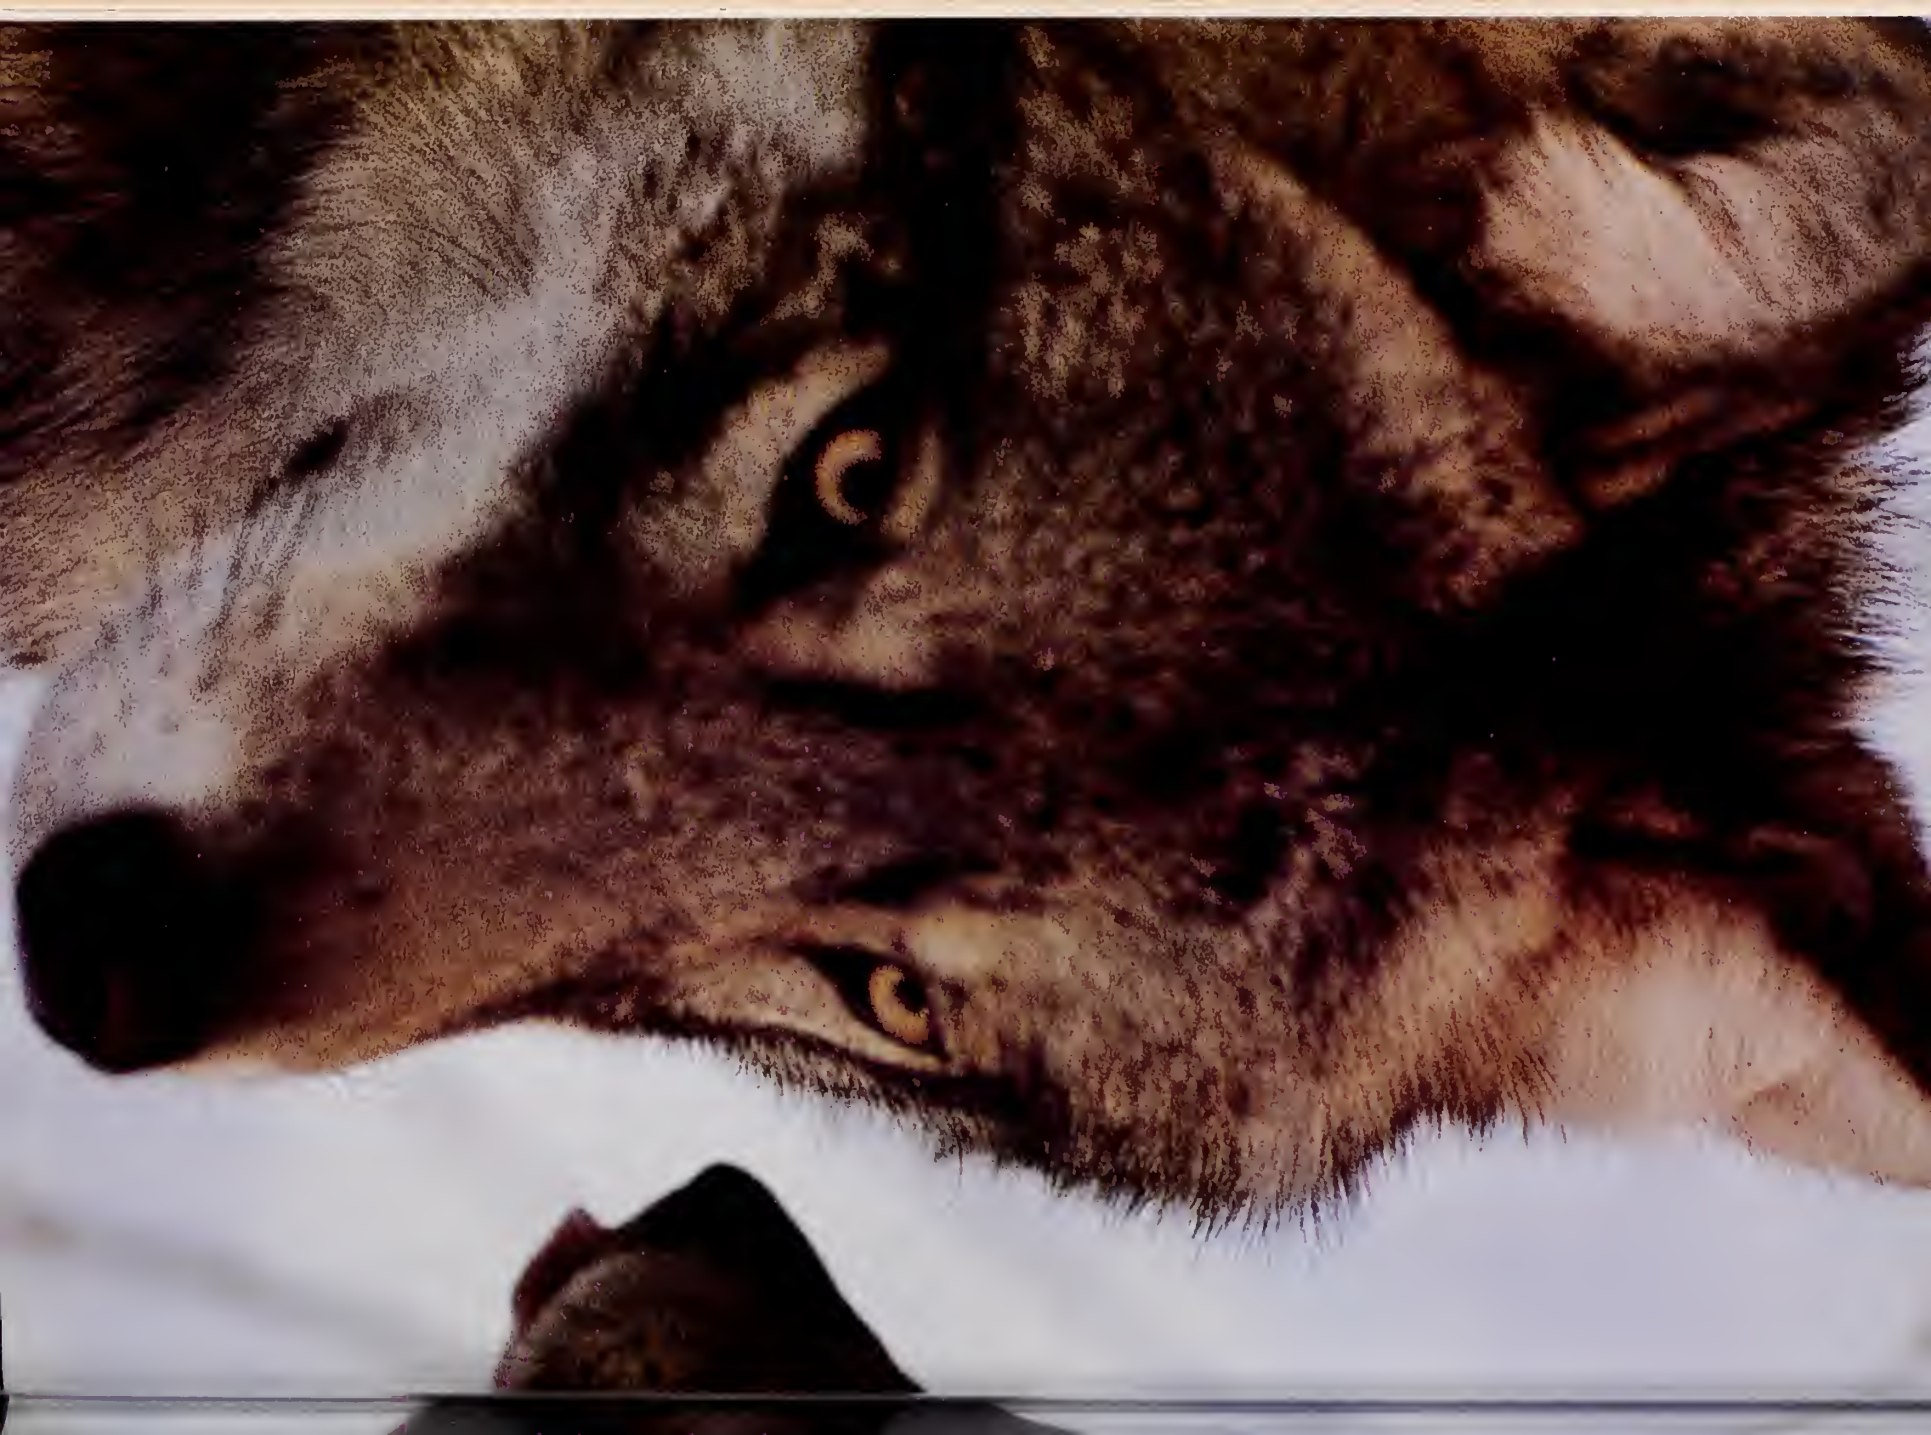
Investigators working in the 1970s observed abnormal accumulations of organic litter in Swedish lakes. The suspected cause was inhibited decomposition due to low pH levels. Several other concurrent studies in North America and Scandinavia, including experiments in stream acidification and lake neutralization, indicate that microbial decomposition is retarded by acidification.

Small algae that live suspended in the water of a lake are called phytoplankton. By means of photosynthesis, these plants reproduce themselves, creating new organic material in the water, a process known as primary production. This process is one of the basic steps in providing energy from food for the animals of a lake. We have already seen that the number of species of phytoplankton is reduced by acidification, but we do not know whether acidification also alters the process of phytoplankton production.

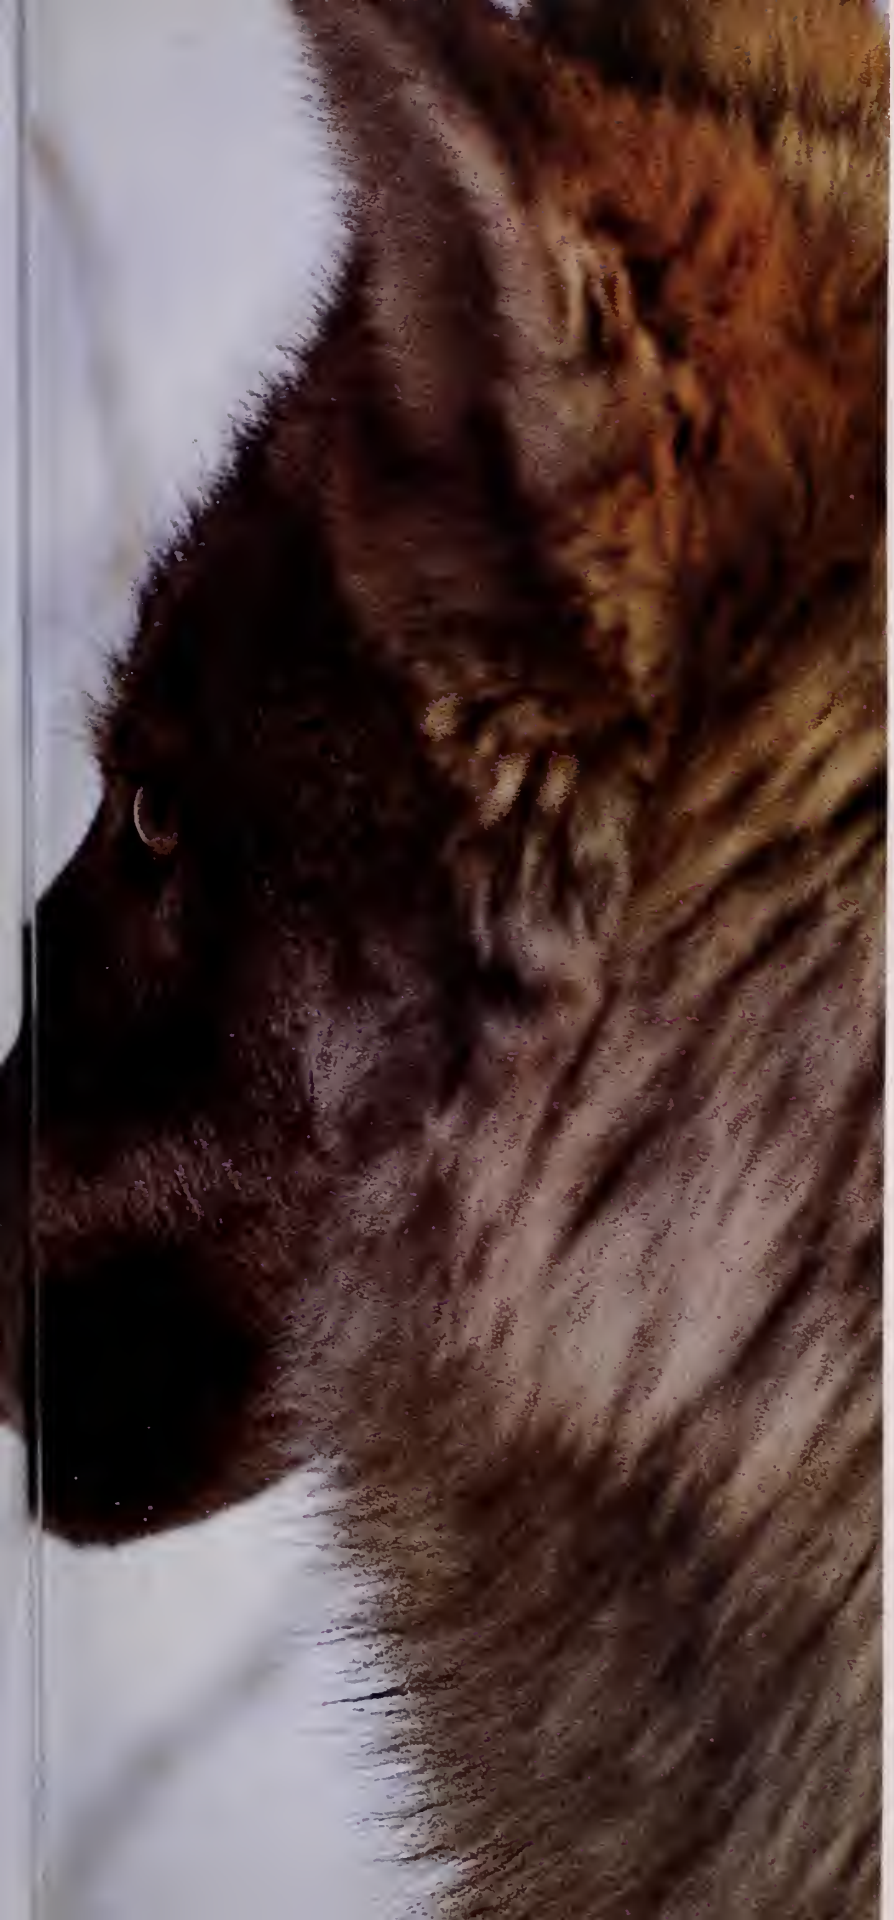
The production of phytoplankton is regulated by the availability of both sunlight and nutrients. In lakes that are sensitive to acidification, the critical nutrient is phosphorus, a key substance regulating plant growth. When the effects of acidification on phytoplankton production in different lakes are compared, it is difficult to tell whether the differences are due to the acid itself, to the presence of other material, such as aluminum, that is increased due to the acid, or to the low availability of nutrients. For most lakes that are susceptible to acidification, the susceptibility arises from their low concentrations of essential nutrients and of various chemicals, such as calcium, magnesium, and bicarbonate. Acidification appears to retard the exchange of nutrients between sediments, decomposing litter, and the water, however, and so in the presence of acidification, nutrients are probably even less readily available. The acidification of watersheds also releases aluminum into the ground water, and aluminum can bind to phosphorus, preventing it from moving through soils. By this process, the supply of phosphorus in streams and lakes may possibly be reduced in acidified watersheds, which would reduce phytoplankton growth. If acidification does reduce phytoplankton production, then part of the foundation of animal life and, consequently, the supply of food for fish, would be reduced.

A side effect of lake acidification is to make lake water clearer. This may result from the acid reducing the brownish color of natural humus materials in the water, from a reduction in the density of algae in the water, or from some combination of these two factors. Algal density would be reduced if the availability of phosphorus was decreased, but whether that decrease actually takes place is not yet known.

Large aquatic plants also seem to be altered by acidification. In some acidified lakes, particularly those studied in Sweden, abnormal and very dense growths of sphagnum moss are found. In Lake Colden, where pH values declined from about 5.5 in the mid-1950s to 4.7 in the summer of 1979, sphagnum, not reported in a botanical survey conducted in the 1930s, is now abundant on the lake bottom. Another development seen in the Swedish lakes, Lake Colden, and many other acidified lakes, is the extensive growth of long, threadlike algae.



Both the sphagnum and the algae form mats that become a tight barrier, sealing off the bottom sediments from the overlying water. Since normal microbial decomposition seems to be retarded by acidification, the underside of these mats may constitute a rich source of organic materials. Low rates of microbial activity eventually consume all the oxygen in this zone, and a new oxygen-free environment develops. Anaerobic bacteria (those that live without oxygen) can thrive there, and although they are slower and less efficient in decomposing material than aerobic bacteria (those that require oxygen), they too decompose the dead plant matter, producing the gases carbon dioxide, methane, hydrogen sulfide, and some more complicated and smelly organic acids and sulfur compounds as their waste products. These wastes erupt from below the algal mat in great bubbles. I suspect that this is the cause of the garbage-dump-like odor that wafts over the surface of some acidified Adirondack lakes during the warmest parts of the year.



In summary, lakes and streams sensitive to acidification are located in regions where the bedrock and overlying soils are deficient in easily weathered minerals and thus cannot provide much buffering capacity to surface waters. Mountainous regions are particularly susceptible to acidification. Many lakes and streams in North America from Florida to Newfoundland have already been acidified. In extreme cases, the biological consequences include the complete elimination of fish and many other species of animals and plants. At intermediate pH levels, the relationships among organisms are likely to be changed in ways that are not yet known but that may exacerbate the problems of freshwater fish life. □

Plant litter in lakes, such as these autumn leaves, is an important source of food for animal life. If the microbial activity that makes this food available to animals is inhibited by acidification, the lake's entire food web may be affected.

Bruce D. Thoma

Italian Wolves

A dog howls in the middle of the night as a lone wolf passes through a sleeping village high in the mountains of the Abruzzi. Otherwise unnoticed, the wolf searches for the food scraps that help it eke out a precarious existence

by Erik Zimen

In 1972, when a compilation was made of Italy's endangered plants and animals, the wolf was at the top of the list. Wolves were not legally protected and could be shot, poisoned, or trapped by anyone, anywhere, at any time. But a campaign conducted by the World Wildlife Fund (WWF), brought a surprisingly swift reaction from the Italian government: the wolf was made a protected species for two years. The effort to save the wolf suffered from a great shortage of information, however. No one knew how many of the animals there were or where they were living, and so it was agreed that the WWF would conduct an inquiry into the distribution of wolves in Italy.

When the WWF offered me the job of conducting the inquiry, I did not hesitate for long. The project would allow me to supplement my investigations of captive wolves with observations of wolves living in freedom. Also, I had often criticized biologists for making scientific studies of different kinds of animals without bothering about the question of their being threatened with extinction. There will be plenty of time for academic inquiries when the urgent practical problem of protecting such species has been solved. So I accepted on the condition that the WWF provide me with an Italian counterpart, namely, my colleague Luigi Boitani.

Luigi and I agreed that attempting to count the wolves in Italy would be a hopeless task. The area that would

Excerpted from *The Wolf: A Species in Danger*, by Erik Zimen. Translated from the German by Eric Mosbacher. © Delacorte Press/New York, 1980

Erik Zimen

have to be investigated was far too big. In the Alps wolves had been exterminated by the end of the nineteenth century, but no one knew where they still survived in the Apennines, which stretch all the way from south of the Po Valley to the southern tip of Calabria. Even if we confined ourselves to the higher altitudes, that would still mean an area of about 27,000 square miles. So we decided that Luigi should first visit all the areas where wolves might still be expected to exist and gain an impression of their numbers and distribution by questioning local people.

He soon found that most of the information he was given was useless. Too many prejudices and lively imaginations led in most cases to the wildest exaggerations. Finally, he concentrated on questioning people who had direct contact with wolves, such as foresters, road workers, hunters, and shepherds, although much of what they told him was contradictory.

The only certainty seemed to be that for several years the wolf had been extinct in both the northernmost and southernmost parts of the Apennines; it had also been exterminated in Sicily. Elsewhere, its distribution seemed to be restricted to about ten enclaves in the higher parts of the Apennines. Luigi felt that because of the density of human settlement and the many roads, highways, and railway lines in the lower areas, there could be no connection between the wolves in these various enclaves. As the estimated number of wolves in some of these areas was very small, it looked as if their extinction there was only a matter of time.

In the only distribution area outside the higher areas of the Apennines, the Tolfa, just north of Rome, the wolves' days seemed to be numbered too. We were surprised that they had survived at all. The Tolfa is an extensive but sparsely inhabited farm region in which good refuge areas for wolves seemed to be completely lacking. That wolves did exist there, however, was demonstrated by the discovery within the city limits of Rome of a young wolf that had been run over by an automobile.

I was eager to begin an actual count. Luigi suggested the Abruzzi, an area in the central portion of the Apennines easily accessible from Rome. On the basis of his inquiries, he estimated that within a 650-square-mile-area in the Abruzzi, there were about twenty-five wolves. The Abruzzi is bounded by the Gran Sasso in the north, Monte Velino and Monte Sirente in the west, the Maiella massif in the east, and the Parco Nazionale d'Abruzzo in the south. There is a strong maritime influence on the climate and, at higher altitudes, an annual precipitation of more than fifty inches. There is precipitation about 110 days each year, and in winter there is generally permanent snow cover above the 3,000-foot level.

While the northern part of the Abruzzi is to a large extent unwooded, thick beech forests cover the steep mountain slopes from 3,600 to 6,000 feet in the central and southern regions. In some places in the national park area, primeval pine forests still survive. Above the forested area there is extensive open pastureland that finally gives way to a bare, rocky high-mountain zone. Below 3,600 feet the common beech gives way to hornbeam and oak. Here, too, there is extensive pastureland, and in the valleys corn and wheat are cultivated. Still lower, at altitudes below 2,000 feet, grapes, as well as other fruits, vegetables, and wheat are grown.

At altitudes of more than 2,500 feet, sheep are kept. The local flocks are small, seldom exceeding two hundred sheep and a few goats. At night the sheep are held in stone sheds in the villages, and when there is no snow on the ground they are driven out to pasture close to the villages. In summer some are taken higher up into the mountains, where they spend the night in fenced pens. In addition to

these local flocks, big flocks from the plain are driven into the mountains where they graze from the middle of June to the end of October. These larger flocks can consist of several thousand animals, and they, too, are guarded by shepherds and dogs in the daytime and kept in pens at night. Thus there is no grazing of the kind practiced, say, in Scotland or the western United States, where sheep are left unguarded day and night, grazing over wide areas. In the past fifty years there has been a steady decline in the number of sheep in the region and a slight increase in the number of cattle. In the summer the cattle graze freely, like sheep in Scotland.

The human inhabitants of the Abruzzi live chiefly in the lower-lying regions, in villages, small towns, and a few larger towns. The population density of the entire province is 202 persons per square mile. At higher altitudes small villages lie in the foothills of the mountain ranges, at heights of up to 3,600 feet. Here there is an average of 75 persons to a square mile. Until the middle of this century there was a high rate of emigration from these areas, and some villages were completely abandoned. But in recent years the development of tourism has led to a movement in the opposite direction, and many emigrants now return from Britain, the United States, and Australia. The big skiing resorts are Roccaraso and Pescasseroli in the national park.

In the southern part of the Abruzzi there is a small population of about 60 to 100 bears, the last in the Apennines. The chamois has been exterminated, apart from about 500 animals in the national park. Roe and red deer were also exterminated, and attempts to reintroduce them in the national park began in 1972. Wild boar similarly had almost completely disappeared, but a slow natural increase in their numbers has now begun. As far as the wolf was concerned, Luigi had reports of them only from the more densely wooded areas of the Maiella and the national park area, and it was there that we began our fieldwork.

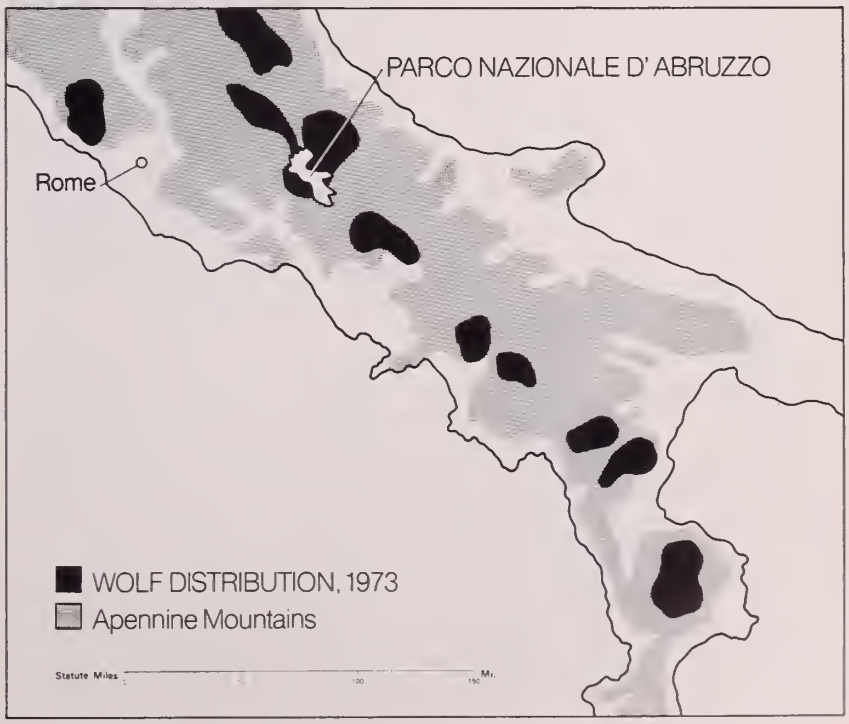
In view of the wolves' great shyness and their secretive way of living, there was no way of studying them other than with the aid of telemetry. Two and a half years of following Abruzzi wolves equipped with radio transmitters showed us a way of life markedly different from that of their counterparts in the wild in North America. North American wolves, which generally travel in packs, cover great distances in their territory, and sleep in a different place every day. Only during the cub-rearing period in summer are their movements star shaped, so to speak, to and from the place where the cubs are. In the Abruzzi, however, this star-shaped activity continues throughout the year. Every wolf (or small pack) had a few places in its territory to which it returned day after day, sometimes for weeks on end. These "traditional resting areas," as we called them, were in areas that were to a large extent inaccessible to human beings, on steep slopes covered with thick beech forest. The distance to the nearest village was not necessarily great, but the places were such that humans rarely went to them.

In winter the wolves kept to lower altitudes, and in summer they went higher up the mountain. We also noticed that in many areas, they remained at higher altitudes on Sundays than they did on weekdays. Many of the lower-lying areas where cars could go were overrun on fine Sundays by

Marka, Photo Reporters

Shepherds lose most of their sheep to wolves during storms and periods of heavy mist conditions or when the sheep are confined in fenced pens. Solitary kills are the most common, although occasional large kills have been reported.

crowds of picnicking Italians, so it was sensible on the wolves' part to keep out of the way. Sometimes we actually had the impression that they withdrew higher up the mountainside early on Sunday mornings, as if they knew the picnickers' invasion was imminent, but that could have been chance.



When darkness fell the wolves emerged from their refuge areas and set out on roamings that took them from one place where food might possibly be found to another. First, they might go to a refuse pit, then a village, then a sheep shed, then another refuse pit. In the morning they withdrew again, often to the place where they had spent the previous day. This was the time of day when we were most likely to see them. In the evening they nearly always waited until it was dark before coming down, but in the morning they often stayed below until the first peasants appeared in the fields. Thus they adapted themselves to a large extent to the rhythm of human activity, which generally lags a few hours behind the state of the sun.

Sometimes the wolves would be late in returning to the mountains from areas of human habitation. In that case some wolves would stay in a hiding place all day long and not move on until darkness fell. For example, wolf 1/2 (the first male we captured, marked with a "1" in the left ear and a "2" in the right ear) occasionally spent the day in a small woods below a village, not a hundred yards from the nearest house. On the other hand, wolf 9/10, a female in the Maiella region, made great detours in order to return to her daytime resting site, the steep rocky slopes at the foot of the Maiella above Santa Eufemia.

The wolves seemed to have an excellent knowledge of human habits. Although food was to be found only in the neighborhood of humans, the wolves avoided contact with human beings as much as possible. In summer, they hardly ever used tarred roads but made good use of tracks and paths. In winter, roads that had been cleared of snow were their favorite routes. Open, unwooded country where the wolves were likely to come across human beings was avoided in the daytime but used at night or very early in the morning. This applied particularly to the summer months, when human activity in such areas was much greater than in winter.

I had an interesting experience with wolf 5/6, a young female in the national park. She was definitely a "refuse-pit wolf," and her favorite daytime resting place was at a steep spot above the Pescasseroli refuse dump. One summer evening in 1974 I followed her from the refuse pit to the ruins of a big hotel above Pescasseroli. The village lay beneath us. I took care not to approach too closely in the car. In the village everything was quiet, except that music was still coming from Pepe's bar. The she-wolf remained above among the ruins. Only when the light went out at Pepe's did she come down into the village. I could not believe my eyes, but she went right on through the sleeping village. While dogs howled frantically all over the place, she crossed the village square and went right down the main street and past the national park headquarters before making off in a southerly direction.

In spite of such behavior, few people in the Abruzzi have ever seen a wolf. Wolves are occasionally surprised by headlights on the main road, but for the most part they are only seen sporadically, by game wardens, forest police, and, of course, shepherds. Even we, who tracked them so closely, saw them relatively rarely. My wife, Dagmar, had been in the Abruzzi for a long time before she saw her first wild wolf, between the tennis courts and the empty swimming pool in the middle of Campo di Giove. In this instance we had tracked 7/8, an old she-wolf, right into the village. When the signal suddenly became very loud, I switched on our big spotlight and soon caught her in its beam. As was quite normal, she took no notice of the light. Headlights obviously did not mean danger to wolves, since we watched them for hours at refuse dumps in the beam of our headlights without their seeming to take any notice. At Campo di Giove the she-wolf 7/8 was looking for something to eat. Down in the valley a passenger train slowly worked its way up the mountain from Cansano, and the illuminated carriages clattered noisily by. The she-wolf was directly below by the rails, but she did not even look up at the passing train. Dagmar saw her second wolf at the Caramanico refuse pit. In this case a fox and a cat were present in addition to the wolf, and as one might expect, the cat kept its distance from the fox and the fox kept its distance from the wolf. The next morning we found that the animals had been eating a big load of slaugh-

Red deer from Yugoslavia and Bavaria were released into the Parco Nazionale d'Abruzzo in the 1970s. The aim is to wean the wolves from their dependence on humans for food by reintroducing their natural prey.

Giuliano Cappelli, World Wildlife Fund

terhouse refuse that had been dumped there.

Thus the wolf seems to have adapted itself admirably to man—its only enemy and at the same time its source of food. It is active when humans—creatures that orient themselves chiefly by sight—are either visually restricted or asleep. This applies not only to nighttime or the season of deep snow but also to daytime periods when visibility is restricted by mist. There is often thick mist on the Passo San Leonardo, and in summer, when sheep graze in the area, the mist brings the wolves. When mist appears, the local shepherds immediately take their small flocks down into the valley and, if visibility is no better there, put them back in their sheds. But shepherds from other regions, who often have no experience with wolves and have big flocks and inexperienced dogs in the bargain, do not always appreciate the danger and fail to collect their many sheep and drive them down to the valley in good time.

It was in such a situation that the first wholesale killing of sheep during our work in the area took place in the summer of 1974. Luigi and I were informed that in the national park 300 sheep had been slaughtered by wolves in the Maiella area. After calling the *carabinieri* station at Santa Eufemia for confirmation, we went immediately to the spot. Unfortunately, we were too late. Because of the danger of an epidemic, 150 dead sheep had already been buried with the aid of a bulldozer. A shepherd who had been present told us that late on the previous afternoon there had been a sudden thunderstorm, accompanied by a thick mist. Two flocks, each of 500 sheep, had been grazing around the half-deserted village of Roccacaramanico on the slopes of Monte Morrone, and they were at once driven down toward the valley. Just as the shepherds were driving the sheep into the pens, five to seven wolves had suddenly appeared. The dogs had run away and the wolves had scattered the sheep.

When the storm was over the shepherds had counted 150 dead sheep in an area of about 250 acres. And another 150, belonging to one of the biggest sheep owners in the Abruzzi, had disappeared. The official veterinarian and the forest police who investigated the incident confirmed this story, so we had no reason to disbelieve it, although the 150 vanished sheep struck us as rather strange. Moreover, the owner of the sheep was a businessman with a doubtful reputation.

At the insistence of the WWF, the Abruzzi authorities had decided that year for the first time to pay compensation to sheep owners for damage caused by wolves, as it was obvious to us that wolves should not be protected at the expense of private individuals. Consequently, the owner of the missing 150 sheep was entitled to full compensation for his losses. Since the sheep in question were said to be particularly valuable animals imported from France, the amount involved was not small.

Two days later news arrived that forty of the vanished sheep had been found. This time we were not too late. The animals, all dead, were lying close to the roadside below the Passo San Leonardo, and under the direction of the forest authorities, some shepherds, and the owner of the sheep, a bulldozer was digging a large hole. We were just in time to stop the burial and have a look at the dead animals. The fraud was evident immediately. The sheep allegedly killed by wolves each had a nice clean slit in the area of the throat, obviously made, not by teeth, but with a knife. Also the gastrointestinal tract, which putrefies rapidly, had been removed from each animal. Some of the animals had certainly been gnawed at, but they had all been killed by humans. Dogs, wolves, and foxes had subsequently been able to eat their fill.

We passed on these observations to the forest police, who were astonished. The owner of the sheep tried to explain to them that it was all the work of wolves, but the whole thing was too obvious, and a new report was drawn up. The sheep owner, who had greeted our arrival in a rather unfriendly fashion, now seemed transformed. A long conversation followed in which I used very hard words indeed. Luigi asked to speak to the owner alone, and he turned out to be far more adept than I. After many hours of discussion, and a good dinner at the hotel up on the pass, the truth came to light. It was finally agreed that for our part we would not make a fuss about the matter, while the sheep owner would not put out poison for wolves. Moreover, he agreed to support our efforts to secure the establishment of a large protected area in the Maiella region; his endorsement promised to be of great importance in view of his political influence.

What had happened? The story of the storm and the raid by the wolves was correct. The wolves had killed some sheep but not 150, and they had not driven away another 150. To increase their compensation the shepherds had killed more of the animals and claimed they had been killed by the wolves. The shepherds had not had these sheep buried but had sold

them, with the sheep that had allegedly disappeared, on the black market to local butchers. One of the butchers had suddenly grown nervous, however, when he saw a number of forest police in the pass. In his anxiety not to be found out, he had dumped his "hot" merchandise, and later the stinking sheep had been scattered about to make it look as if they had been killed by wolves.

This was certainly not the only attempted fraud in this first year of compensation. Altogether nearly 38 million lire (about $70,000) was paid out in the Abruzzi in 1974. We estimated that at least half the reported kills were either outright inventions or the work, not of wolves, but dogs. Similarly, Franco Tassi of the national park estimated that the real damage done was from 20 to 30 percent of what was claimed. In following years the conditions for paying out compensation were made stricter at our suggestion. Only killings actually identified as such would qualify, shepherds had to have a sufficient number of dogs, and one shepherd could not be in charge of more than a hundred sheep. This last requirement could easily be met by local shepherds, but because it was hard on those who came with their big flocks in summer, it was not strictly enforced. As a result the forest administration began building big, secure pens in the mountains that neither wolf nor bear could enter. Overall, compensation payments greatly diminished.

While sheep are constantly watched, cows and horses graze freely, and on several occasions I saw wolves making their way through herds of cattle or horses without these animals taking any notice and without the wolves showing any sign of wanting to attack them. To the wolves, which are relatively small in the Abruzzi and run only alone or in small packs, cattle and horses are simply too big. It was only rarely that we could be sure that a dead calf or foal had been killed by a wolf. In most cases the young animal had been separated from its mother. With horses, the mother was always hobbled. This is a normal practice that makes the horse easier to catch, but it is a handicap against wolves, and many foals have paid for it with their life.

By far the largest number of sheep killed while we were working in the area were solitary animals. At night wolves crept up to the fenced pens and

If you'd like to know more about charcoal mellowing, drop us a line here at the distillery

IT'S EASIER TO UNDERSTAND how we charcoal mellow Jack Daniel's, after you've peered inside a charcoal mellowing vat.

We can show you how tiny drops of Jack Daniel's trickle slowly through room-high vats of tightly tamped charcoal. And we can tell you that nothing (not even aging) gives our whiskey more smoothness. After you've looked inside a charcoal vat, you'll always remember how we use them. After a sip of Jack Daniel's, we believe, you'll be glad we always will.

¡Speak Spanish like a diplomat!

What sort of people need to learn a foreign language as quickly and effectively as possible? *Foreign Service personnel*, that's who. Members of America's diplomatic corps are assigned to U.S. embassies abroad, where they must be able to converse fluently in every situation.

Now *you* can learn to speak Spanish just as these diplomatic personnel do with the Foreign Service Institute's Programmatic Spanish Course.

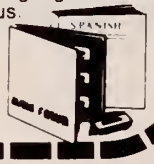
The U.S. Department of State has spent tens of thousands of dollars developing this course. It's by far the most effective way to learn Spanish at your own convenience and at your own pace.

The Programmatic Spanish Course consists of a series of tape cassettes and an accompanying textbook. You simply follow the spoken and written instructions, listening and repeating. By the end of the course, you'll find yourself learning and speaking entirely in Spanish!

This course turns your cassette player into a "teaching machine." With its unique "programmatic" learning method, you set your own pace—testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Programmatic Spanish Course comes in two volumes. You may order one or both courses:

☐ Volume I, Basic.
(11 cassettes, 16 hours), instructor's manual and 464-page text, $115



☐ Volume II, Intermediate.
(8 cassettes, 11½ hours), instructor's manual and 614 page text, $98
(New York residents add sales tax.)

Your cassettes are shipped to you in handsome library binders.

TO ORDER, JUST CLIP THIS AD and mail with your name and address, and a check or money order. Or, charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

The Foreign Service Institute's Spanish course is unconditionally guaranteed. Try it for three weeks. If you're not convinced it's the fastest, easiest, most painless way to learn Spanish, return it and we'll refund every penny you paid! Order today!

Many other FSI language courses also available. Write us.

helped themselves to a sheep, which they generally dragged outside and ate there. Local shepherds also reported the loss of single animals that went astray in a thick mist or on the way home. Many of these were eaten on the spot, with only their skin and heavy bones left over. It was not uncommon for wolves to leave behind animals that had been only nibbled at, however, presumably because they had been disturbed. The remains were generally eaten by dogs the following day.

Yet we also saw damage on a larger scale. It was not uncommon for as many as ten sheep to be killed, and on two occasions more than a hundred were dispatched. This always seemed to happen when panic broke out among the sheep and a large number ran about bleating wildly. To the wolves the activity was an irresistible signal to catch and kill, and like foxes in a chicken run, they killed everything they could. (A bear is said to have broken into a sheep shed in the national park, killed the more than one hundred sheep in it, and then gone to sleep out of sheer exhaustion, so that the next morning the shepherds found him asleep among the dead sheep.)

Such excesses of killing arise in the unnatural situation in which a predator is confronted with a large number of prey animals whose movements are restricted. In complete contrast to the killing of wild prey, nearly all of which is consumed, predators kill more domestic animals than they can use. Erki Pullainen reports similar findings from northern Finland. Of 149 sheep, 9 cows, 15 calves, and 3 horses killed by predators, only 31 sheep, 3 cows, 5 calves, and 1 horse were eaten.

This behavior is what causes the shepherds' very understandable hatred of predators, the wolf in particular. Losing a single sheep, a single foal, or a single calf on occasion would perhaps not be so bad. But for a predator to kill a hundred or more animals and then not even eat them is too much. Whenever a wolf has killed in this manner, the event has been widely reported in the newspapers, and hostility both to wolves and to the movement to protect them has become vociferous.

On the other hand, when a wolf meets a violent death, newspapers and television also report the event with horror, as happened when Luigi and I found 1/2, the first wolf we had tagged, dead in a stream in the na-

tional park area. The animal had obviously been killed with a shotgun by a poacher who had been shooting birds. It must have taken some time to die. Its body was carried along by the stream and finally ended up in the undergrowth by the bank where, guided by the transmitter, we eventually found it.

Other wolves marked by us also died at the hands of humans. At the very beginning of our work in the Maiella area we caught and tagged two adult females from neighboring packs. At least four other wolves, presumably an adult male and three cubs, were living with one of these females (7/8). The female had cubs again in the spring in a thick woods on the Cresta Maggiore above Cansano. Luigi found the den and saw two cubs, although there may have been more. This den was the rendezvous for the pack throughout the summer. In the winter that followed I succeeded in catching and tagging two adult males and two nine-month-old cubs, so that there were four members of the pack we could keep track of. Together these wolves roamed an area of about seventy-five square miles between Sulmona, the Passo San Leonardo, and Pescocostanzo. It was not long, however, before we found one of the cubs dead: it had swallowed strychnine hidden in the carcass of a sheep. And one of the adult males died soon after, also of strychnine poisoning.

Of the total of twenty-five wolves that we knew had died in the Abruzzi from 1974 to 1976, at least nine, chiefly young ones, died of poison. Three died of gunshot wounds and one was run over. For the others the cause of death could not be established. We have no information about wolves that die of natural causes—illness, old age, wounds, or undernourishment. But since of an estimated total of twenty-five wolves at least thirteen, and probably more, were killed in the course of two years, the chances of natural death cannot be very high.

Because of the wolf 's secretive way of living, we were not able to obtain an accurate picture of the nature of the population, that is, its age structure, the size of its social groups, its rates of reproduction, and so on. Observation of 7/8 and her pack showed that wolves in this area were able to form small packs, which remained stable for a time, and to lay claim to a territory that was defended against strange conspecifics. But the high death rate due to human agency, as well as living conditions that are greatly dependent on human beings, affects the spatial organization of the population, and such packs do not survive for long. The large amount of food required by young animals and the consequent increased pressure on domestic animals (when cubs are present) result in an increase in human persecution when a pack has been formed. The result is a surviving wolf population largely split up into small groups or individual animals that generally live on refuse and are able to reproduce and rear cubs successfully only in exceptionally favorable circumstances.

Our work in the Abruzzi showed very plainly the demands that the wolf makes on the living space it shares with humans. Apart from a sufficient food supply, a matter on which it is not exactly choosy, the wolf needs refuge areas that are to a large extent free of human disturbance. These can be either undeveloped forest areas or mountainous regions with forests and steep ravines. In any case, in the Italian distribution area we found no region where woods or mountains were lacking and wolves survived. In this

connection the effort of the Italian forest administration to reforest many cleared mountain regions is certainly a positive factor.

To conclude our work in the Abruzzi, my wife and I flew along the Apennines from Florence in the north to Calabria in the south. We wanted to find out what the country looked like in between the high mountain areas where Luigi had originally concluded that wolves still survived. We spent four days crisscrossing the mountains, and found no distribution area that seemed to be completely isolated from the rest. Thus, according to the present state of our knowledge of their behavior, wolves should be able to roam from Monti Sibillini in the north of the Abruzzi to Monti della Sila in the south. That would make their final extinction in Italy more unlikely than we had originally supposed.

It soon became clear to us that their survival, whether they lived in isolated enclaves or in contact with one another, depended on doing away with their total reliance on humans. This could be accomplished only by large-scale reintroduction of their natural prey. The red deer was exterminated in the Abruzzi in the nineteenth century, but a small population of roe deer survived in the national park area up to the 1960s. The principal cause for the disappearance of both species must have been hunting, although the competition resulting from overintensive grazing of domestic animals may also have played a part.

In 1971 and 1972 a total of forty-five red deer from Yugoslavia and twenty-one roe from northern Italy were set free in the national park. When our project began a year later, little was known about their whereabouts. The red deer had evidently established themselves in the vicinity of their point of release, but the roe seemed to have disappeared again.

We therefore proposed that more animals of both species should be released and that they should be studied with a view to gaining knowledge and experience for further large-scale reintroductions. We were particularly interested in how they would multiply, the influence they would have on the vegetation, and their interactions with domestic animals, as well as with the wolf and the bear. Between 1974 and 1977 a total of twenty-eight red deer and sixteen roe were released at various places in the national park. The

deer all came from the Bavarian Forest National Park, presented by the Bavarian Ministry of Agriculture as part of a joint operation between the Abruzzi and Bavaria. This certainly reflected credit on the minister of agriculture, who exposed himself to severe criticism from the political environment from which he came. The press talked of "German deer for Italian wolves," and the sporting community was not exactly friendly either.

Critics frequently cited Italy's annual "massacre of birds" as a reason to abandon the project, claiming that as long as such a disgraceful state of affairs prevailed in the country, "ecological development aid" should not be granted in other areas. But these arguments do not hold water. Certainly a stop should be put to the shooting of millions of birds, including migratory species, that takes place in Italy each year. Nobody is more aware of that than the Italian conservationists. The Italian shooting of birds has become ecologically intolerable. But even this massacre is not as bad as depriving species of their living space by draining the last marshes, straightening the course of rivers, turning natural forests into pine plantations, and making wholesale use of poison in agriculture and forestry—all because of the compulsion to exploit every last square foot of land in Central Europe.

Our object in introducing deer was not merely to supply wolves with living meat, but to reestablish ecological conditions destroyed by human beings, including hunters. Not only should wolves have their natural prey, but red deer and roe should get back their natural predator—an act of ecological "reparation" that we hoped would benefit the disrupted living community of the selected territories.

The deer established themselves well. In the summer of 1976 there were already 130. At first they settled in the surrounding valleys, but soon some individual animals had advanced as far as the neighborhood of Sulmona. We know little about the effect they have had on the vegetation. In the national park area I saw large areas of willow herb that had been stripped bare. But in areas where there is no grazing of domestic animals, the vegetation is so luxuriant that there would still be a place for a great many more deer, and even in grazing areas it should be possible to maintain a limited number.

the national park we found the remains of three deer killed by wolves. One was a weak female that had been killed soon after being released, and the other two were young males that had been cornered by the wolves in impassable woodland. But the growth of the population shows that the wolves exercise little regulatory influence. The deer are presumably too big, in general, to be brought down by a single wolf or even a small pack. It would be interesting to investigate possible changes in the social organization of the wolf resulting from adaptation to the new kind of prey.

There is no doubt that unless fundamental changes are made soon the days of the wolf are numbered in the Abruzzi, as elsewhere in Italy. In the course of our fieldwork the necessary changes became very clear to us. All hunting of wolves would have to cease, as would the use of poison to combat foxes or other wild animals. Moreover, no more refuge areas vital to the wolf could be destroyed by the building of roads and ski lifts. Thus our primary concern was to secure action at the legislative level, although it was clear to us that the best laws would be of no avail unless the wolf was accepted by the local population. Hence we had to investigate the attitude of people in the locality and discover the conditions under which they would be willing to accept the wolf.

We made our first efforts in this direction when we began work in the area in March of 1973. Our methods of interrogation would not have been regarded as scientifically acceptable in sociological circles, but we asked a number of people whether they thought wolves were dangerous to human beings. Our "impressions" (I use the term to avoid saying "findings") were interesting. The farther we were from the areas in which wolves lived, the more dangerous they were believed to be. In areas inhabited by wolves the people least impressed by the animals' alleged dangerousness were those who had direct contact with them. All the shepherds we asked agreed that the wolf was not a threat to human beings. The occupational group that regarded the wolf as especially dangerous was, interestingly enough, innkeepers.

Our impressions were confirmed two years later by a proper scientific inquiry we conducted in cooperation with the Sociological Institute of the University of Rome. The questioning

took place in a number of villages in the Maiella area. By that time our work with the wolves had been given a great deal of publicity, most of it favorable. Besides a number of television films, there had been many reports in the press, the local radio station had shown a great deal of interest, and Luigi had delivered a number of lectures. So there was practically no one in the area who did not know us or, at any rate, our Land Rover, which with its impressive array of aerials was on the move by day and by night. Our campaign, as well as that of the WWF, against plans to establish a new ski resort on the Passo San Leonardo was also known. Instead of a ski resort, we proposed the establishment of another national park or at least a regional park in the Maiella. Hunting would be forbidden there, and red deer and roe would be introduced. Instead of building big hotels financed from Rome and Milan, we suggested that the beautiful old villages should be restored, facilities for overnight visitors extended, and small pensions established. Our proposals looked rather unfashionable in comparison with the spectacular plans to develop the Maiella with ski lifts, a golf course, hotels, and holiday homes, but they would benefit the local people, and the kind of tourism they would attract, although it would bring in less money, would not be so seasonally limited.

The inquiry showed very clearly that people's attitude toward the wolf depended largely on their interest in the various possible alternatives for the future development of the area. Those who lived in the lower-lying areas, who would neither suffer damage from the wolf nor benefit from the development of the Maiella into a ski track, were generally in favor of the wolf and its protection. The cultural aspect—the desire not merely to exterminate a creature that had made such a mark on the history of the area—played an important part. Surprisingly, even shepherds were favorably inclined to the wolf. Indeed, they had no objection as long as the number of wolves did not get out of hand and compensation was paid for any damage they suffered. They also favored the idea of introducing red and roe deer, which would relieve wolves' pressure on their sheep.

I find this attitude on the part of the shepherds quite remarkable. In spite of the traditional warfare between wolf and shepherd, the shep-

While the thrill of mastering a spiny Alpine road in the BMW built for it remains as potent as ever, we recognize that these are value-conscious times.

Chino Pants
(For Men and Women)

You'll get more wearing pleasure from these pants than any others you own. Made of high grade combed cotton/polyester twill. Permanent crease, washable. No ironing required. Neat looking for sports or work. Color, Light Tan. Men's waist sizes: 24, 25, 26, 27, 28, 29. Inseams 30″ and 32″. Even waist sizes 30 to 44 plus 31 and 33. Inseams 29″, 30″, 31″, 32″, 33″ and 34″.

Lined Chinos

Same sturdy construction but fully lined with our famous tan Chamois Cloth, a comfortably warm 100% cotton flannel. Men's even sizes 30 to 44. Inseams 29″, 30″ and 32″. Women's even sizes 8 to 20. Inseam 31″.

L. L. Bean, Inc., 702 Casco St., Freeport, ME 04033

herds' attitude was one of tolerance. Hunters, however, were less favorably inclined. Although the wolf was hardly a competitor for "their" prey, their attitude was negative, and they frequently complained about the damage done to domestic animals. Finally, those who hoped to benefit from a skiing circus on the Maiella were definitely opposed, either because they wanted to build hotels or because they owned land they hoped to sell at a high price. The people of Pacentro, in whose communal area the ski lifts and hotels were to be built, were particularly hostile. The woman who conducted the inquiry was once actually thrown out of the village as a Communist agent.

People in the villages through which we often drove, many of whom knew us personally, were much more favorably inclined, although here too their attitude basically depended on where their interests lay. Indeed, there were people with whom we were on the best of terms and who were accessible to our arguments who, if they could, would have hunted down every last wolf.

The inquiry showed plainly that conservation work cannot succeed in the long run if it is against the interests of the local people, however questionable those interests may be. Rather, a conservation effort must attempt to get the majority of the population on its side by a conciliatory approach, by putting forward alternative development plans, by a willingness to pay compensation for lost rights, and by a great deal of factual explanation that does not attempt to conceal the existence of opposing interests. People should not be allowed to feel that conservationists are going to decide what is to happen in their neighborhood without consulting them. Instead they must be persuaded that conservationists consider the interests of the neighborhood as well. This may prove to be a long, difficult, and thoroughly political task, a fact not always sufficiently understood in conservation work. I believe that in the Abruzzi we succeeded in at least making a start at integrating our conservationist goals into an alternative view of ecological and economic development that will ultimately be more beneficial to the people of the area.

But it is not only at a local level that the future of the wolf and the values for which it stands will be de-

Enter the world of Questers nature tours.

When you travel with Questers, you have the advantage of our knowledge of the travel world. And our experience of the natural world. We are travel professionals. And our only tour program is Worldwide Nature Tours.

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers... rain forests, mountains, and tundra... seashores, lakes, and swamps of the regions we explore. At the same time, we include the more usual attractions in touring—the cities, archaeological sites, and people.

The current Directory of Worldwide Nature Tours describes 29 tours varying from 9 to 36 days and going to virtually every part of the world. Included are The Amazon, Peru, Patagonia, Galapagos, Hawaii, Alaska, Death Valley, Everglades, Ladakh, Sri Lanka, Iceland, Scotland, Greece, Australia, and New Zealand. Tour parties are small, the pace leisurely, and itineraries unusual.

Call or write Questers or see your Travel Agent today for your free copy of the Directory of Worldwide Nature Tours.

sential role. In this respect Luigi and the WWF succeeded in attaining two objectives that are vital to the survival of the wolf. Shortly before my departure from Italy in December 1976 the Agriculture Ministry in Rome made the wolf a permanently protected animal throughout the country and prohibited the use of poison for predator control. We were especially pleased by this last prohibition because it was so unexpected and so important, not only to the wolf.

What does the future hold for the wolf in Italy? Everything depends on how these two laws are observed. And that depends on the attitude of the local population, which in turn depends on the future economic development of the higher-altitude areas in the Apennines. If compensation regulations were introduced in the southern provinces, as they have been in the Abruzzi and more recently in some other provinces, another step in the direction of tolerance would be taken. A reasonable development of tourist facilities would presumably also be beneficial, since the economic base would be broadened and the great dependence on sheep, which has prevailed in the past, would be diminished. Economic prosperity is certainly one of the essential conditions for the preservation of the wolf. But every mountain need not be equipped with skiing facilities and every village need not have a big hotel. This would be not only an ecological disaster for the wolf and other free-living animals but also an economic dead end for the people of the area.

Finally, the future of the wolf depends on the success of the prey introduction program. Whether red and roe deer will be able to survive outside strictly protected areas, such as the national park, depends on Italian sportsmen. This is certainly a factor of great uncertainty, and I must admit that my hopes in this respect are not very high. Deer and chamois are strictly protected, and the penalties for shooting them are severe. But who is to insure that the law is enforced? Our hopes lie with the forest administration, whose attitude toward introduction is very positive. Also the sportsmen of central and southern Italy do not have a tradition of hunting ungulates, and shooting in the forest is prohibited. Perhaps, after all, there is a chance that deer, wolves, and human beings will be able to coexist in developed and cultivated areas. □

ALASKAN WILDLIFE ADVENTURE

June 26 to July 9, 1981

Join Kenneth A. Chambers, Lecturer in Zoology at the American Museum, for a journey to America's last great frontier. Cruise through fabulous Glacier Bay, with its whales, seals, and teeming birdlife. Explore scenic Mt. McKinley National Park, and see giant moose, white mountain sheep, barrenground caribou, and golden eagles. Visit volcanic Katmai, and watch brown bears fishing for salmon. Fly to the remote Pribilof Islands, summer home to over a million fur seals and countless nesting sea birds. Limited to 25 participants.

Seyfert Galaxies

These peculiar objects resemble quasars in many respects, and they are equally puzzling

by Eugene R. Capriotti

Next to the sun, the moon, and Saturn, the spiral galaxies, because of their distinctive structure, are the most easily recognizable of astronomical objects. Billions of these flat pinwheels, each containing hundreds of billions of stars, are strewn throughout the universe.

The spectrum of a spiral galaxy is generally what one might expect for an object containing a myriad of individual stars. A small percentage of spiral galaxies, however, in addition to a composite stellar spectrum, have spectral features that cannot be produced by a conglomeration of isolated normal stars. These nonstellar spectral features are produced by hot ionized gases having a wide range of density and excitation. The first spiral galaxy with these special features was discovered in 1943 by Carl Seyfert, then working as a postdoctoral fellow at the Mount Wilson Observatory in California. Each similar object that has subsequently been discovered has been called a Seyfert galaxy. The most distinctive structural feature of the Seyfert galaxies is that they have very small, extremely bright central regions called nuclei in which their peculiar spectra are produced.

Little attention was paid to the nuclei of Seyfert galaxies until after Maarten Schmidt, an astronomer working at Palomar Mountain in California, showed in 1963 that quasars have extremely large spectral red shifts, indicating that they are receding from us at speeds approaching the speed of light. Interest in quasars, on the other hand, has practically dominated extragalactic astronomy since the early 1960s, and it is the resemblance of the nuclei of Seyfert galaxies to quasars that has generated a great deal of interest in the Seyfert galaxies as well.

What makes the quasars so interesting is that their very large spectral red shifts are probably due to the recessional velocities associated with the general expansion of the universe (see "Quasars Confirmed," *Natural History,* February 1980). If that hypothesis is so, quasars, as a class, are the most distant objects in the universe because, as a class, they have the greatest spectral red shifts. If the quasars are very far away, then they are generating energy at a rate far in excess of the rate of energy production of a normal spiral galaxy made up of hundreds of billions of stars.

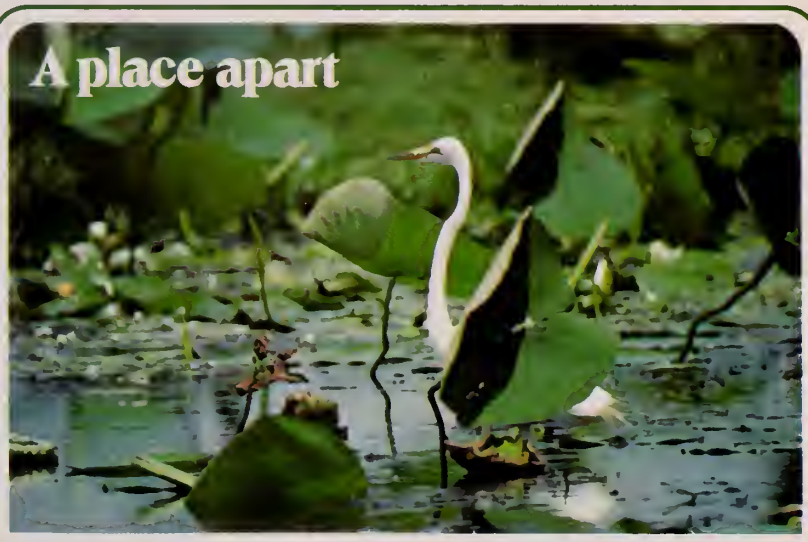
Quasars are also extremely small by galaxy standards. The brightness of some of these objects varies greatly over periods of time as short as a few weeks, consequently their diameters can be no greater than the distance traveled by light in the same time. This distance is about 100 times smaller than the distance from the sun to its nearest neighbor star, which is about four light-years away. In comparison, the diameter of our Milky Way galaxy is about 100,000 light-years.

The problem with the quasars is to understand how relatively compact objects generate more power than an entire galaxy of stars. That is also the problem with Seyfert nuclei, which in many cases produce more power than their parent galaxies. Scientists believe that if the question of energy generation in the nuclei of Seyfert galaxies were to be solved, the problem of energy generation in quasars might be solved automatically. Because of their similarity to Seyfert nuclei, quasars are viewed as being extremely bright.

nuclei of galaxies too far away for any part of the galaxy other than the nucleus to show up on photographs. In short, quasars can be considered to be very distant Seyfert galaxies, and Seyfert galaxies can be considered to be relatively nearby quasars.

Quasars are generally more luminous than Seyfert nuclei. As a class, however, the quasars are more distant than the Seyfert nuclei, which means that because of the finite speed of light, the energy generated by quasars reveals an earlier epoch in the history of the universe than does light coming from Seyfert galaxies.

The rate at which energy is generated in an active nucleus of a galaxy may depend on the age of the parent galaxy; perhaps the younger the galaxy with an active nucleus, the more luminous the active nucleus. In addition, since the quasars are so distant, the fainter ones are difficult to spot and the average luminosity of quasars might tend to be artificially enhanced by the observational selection of the brighter ones. In any case, the belief persists that quasars and Seyfert galaxies are different in degree but not in kind.



Theories attempting to account for the activity in the nucleus of a galaxy begin with the idea of a large mass concentrated at the center of the galaxy. Observational evidence of both Seyfert galaxies and quasars points to the accumulation of such a mass in a region with a diameter no larger than one light-year across and the mass being between one million and one billion times the mass of the sun. That is a very small area for a mass of such dimensions. The three basic forms of mass concentration upon which the various theories proposed

Smaller can be better, as the new full-power Nikon Roof Prism Compact Binoculars clearly demonstrate. Pocket-size slim and just 7-1/2 ounces light, they outperform many bigger and heavier binoculars in sharp, bright, distortion-free viewing. You see the entire scene, even while wearing glasses. And, most important, they're so precisely engineered that you can view for extended periods, without strain or discomfort. Available in all-purpose 6x, 7x and 8x models. See the difference Nikon quality makes, at Nikon camera dealers and selected optical departments. Or write to Nikon Inc., Dept. N-26, Garden City, New York 11530. Subsidiary/Ehrenreich Photo-Optical Industries, Inc.

for active galactic nuclei have been based are: (1) a dense star cluster, (2) a supermassive star, and (3) the accretion of material onto the perimeter of a black hole—a black hole being a concentration of mass with a gravity so strong as to prevent the escape of anything, including light.

There are two ways in which energy might be generated by a dense star cluster at a rate far in excess of the rate at which energy is produced by the normal nuclear processes that occur in the member stars of normal clusters. If the cluster is dense enough, collisions between its member stars could take place, causing the stars to break apart and thereby release energy at a rate in excess of the rate at which the stars normally shine. In such a case, the rate of energy production could even be far in excess of the rate of energy production of an entire galaxy of stars.

However, a sufficiently high rate of energy production is not the only criterion that must be met in order to explain the activity in a quasar or the nucleus of a Seyfert galaxy. The concentration of mass must also be able to provide the necessary power for the estimated lifetime of the active stage. If the extreme activity that occurs in the nuclei of Seyfert galaxies occurs in all spiral galaxies sometime during the lifetime of the galaxy, then the percentage of Seyfert galaxies would be the same as the percentage of the time that any spiral galaxy spends in the active stage. Present estimates indicate that about one percent of spiral galaxies are Seyfert galaxies. That means that if a spiral galaxy does in fact live for about ten billion years, as we believe, the active stage of the galaxy lasts about one percent of that time, or for one hundred million years.

In the case of dense star clusters, the necessary rate of energy production apparently would not be sustained for the necessary length of time. The cluster, continually losing energy through star collisions, would condense into a supermassive star or a black hole in a period of time shorter than that required to account for the frequency with which the galactic activity is observed.

Another possibility involving dense star clusters that has also been explored is the coalescence of stars due to collisions. In this picture, the more massive stars of the cluster merge into bigger and bigger stars by colliding

NH020

with each other. As these stars grow, they eventually reach the stage at which they become unstable and explode in supernovae outbursts that supply energy to the galactic nucleus.

The problem with this theory of coalescence by means of collisions is similar to the problem with the theory of disruption due to collisions. As a consequence of developing a concentration of stars sufficient for the necessary collisions to occur, the cluster or part of the cluster would have to shrink into a single supermassive star or a black hole in a period of time shorter than the period necessary to account for the frequency with which the active galactic nucleus is observed.

The conclusion is that dense star clusters may be the precursors of quasars and Seyfert nuclei, but that the phenomenon of actual active galactic nuclei must be related to one of the other two forms of enormous concentrated mass that have been proposed, namely, supermassive stars or black holes.

The mass concentration that was first considered as a possible source of quasar energy was in fact the supermassive star. The relation between the rate of energy emission and the mass of a supermassive star is well known and the power necessary for an average active galactic nucleus could be provided by a supermassive star with a mass of about ten million suns. (If an object of that mass were in the sun's position relative to the earth, its radiant energy would create a temperature of about 50,000° F on the earth.) The most luminous quasars could be powered by a supermassive star with a mass of about 500 million suns. However, a supermassive star of these proportions would not be stable. Calculations show that a supermassive star having a mass of more than about 700,000 suns would collapse irreversibly unless it were rotating so rapidly that it would become flattened and so fractured that it would probably no longer have the characteristics of a star.

Thus, the concentration of mass into a supermassive star capable of powering an active galactic nucleus would apparently almost immediately result in collapse into a black hole. Since a dense star cluster of sufficient mass to power an active galactic nucleus would ultimately produce a supermassive star or a black hole, and since a supermassive star of such proportions would in a very short time col-

© 1981 Garden Way Inc

lapse to the state of a black hole, many astronomers have argued that black holes are present at the centers of active galactic nuclei. A central, massive black hole could then power these galactic nuclei through the accretion of material from the space between the member stars of the parent galaxy.

The basic idea regarding the accretion process is that material from the galaxy spirals into the central region much as water spirals into a drain. Some theories concerning the growth of black holes picture the material spiraling directly into the hole with each particle releasing as much as 20 percent of its mass energy as it disappears into the hole at nearly the speed of light. Other theories of black hole accretion picture the material accumulating into a disk that rotates around the black hole, with matter leaking into the hole from the inner rim of the disk. In the latter case, energy is generated by material falling onto the disk as well as by material pulled into the black hole.

Some astronomers believe that all spiral galaxies have black holes at their centers and that all galaxies are active to some degree, depending on the rate at which material is pulled by gravity into the black holes. Nevertheless, the inference that the observational properties of quasars and Seyfert nuclei can be entirely explained by a theory involving the presence of black holes should not be made because active galactic nuclei contain some features that are not easily accounted for in terms of black holes. In particular, there are broad emission lines in the spectra of these objects that can be adequately explained in terms of radiation from gas clouds moving radially outward at several thousand miles per second in a manner indicating that the clouds were hurled outward in an explosive event. Massive black holes do not explode and it is difficult to see how an accretion disk could explode because it dissipates, rather than builds up, energy.

Perhaps the quasar and Seyfert nuclei phenomena are not steady, long-term events that occur over periods of as much as 100 million years. Instead, they may be recurring explosive events. In the latter case, black holes cannot be favored over other large concentrations of mass merely because of their long-term stability. In fact, an instability that leads to an explosion might be the necessary property of

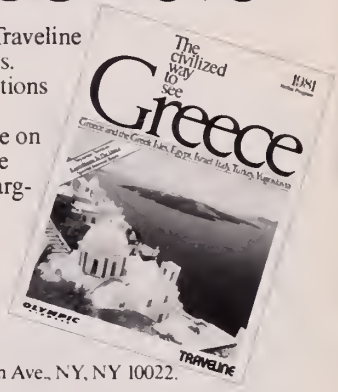
a large concentration of mass that supplies the energy for active galactic nuclei. Supermassive stars with masses of between about 500,000 suns and masses of about 700,000 suns have just that property. They are unstable, but instead of collapsing into black holes, as do supermassive stars having masses greater than 700,000 suns, they suffer violent nuclear explosions.

In each explosion, enough energy would be released to power a luminous Seyfert galaxy for about 30,000 years. Not all the energy of the explosion would be expected to be converted to radiant energy, but even if only 10 percent were, there would be enough energy to power a Seyfert galaxy for 3,000 years. Since the activity in the nucleus must go on for a total of 100 million years, then 30,000 repetitions of a supermassive star outburst would have to occur. The material at the center of spiral galaxies would have to grow into a supermassive star with a mass of about 500,000 suns in order to cause a violent explosion. Therefore the total amount of material that would have to be processed in order to power a luminous Seyfert galaxy would be equal to the mass of ten billion suns.

A mass of ten billion suns is about 5 percent of the mass of a normal spiral galaxy such as our Milky Way. In order to power a luminous quasar, all the mass of a normal galaxy would have to be processed, a quite unlikely situation.

There are many ifs and maybes, however. Maybe the parent galaxies of quasars are much larger than normal spiral galaxies. Maybe the quasars are not as long-lived as the Seyfert galaxies and don't have to process as much material as it seems. Whatever the case, the mechanism by which the energy of the active nuclei of galaxies is generated is not at this time well understood and our theories regarding the accretion of black holes and the explosions of supermassive stars must be classified as speculation.

Astronomers studying quasars and Seyfert galaxies continue to provide observational data. As these data are analyzed, we hope to come closer to a true understanding of how the nuclei of these objects really work.



Eugene R. Capriotti is chairman of the Department of Astronomy at Ohio State University and director of the Perkins Observatory of Ohio State and Ohio Wesleyan Universities.

Greece. Our biggest, most civilized book ever.

Other brochures offer slices of Greece. Traveline gives you the whole Greece. Athens. Isles. Cruises. Classical Greece. Plus combinations with Israel, Egypt, Turkey or Italy.

All vacations include *scheduled* service on the No. 1 airline to Greece, Olympic. See your travel agent or Traveline—world's largest designer of tours to Greece.

It's the only civilized way.

NH—Feb.

"A seminal study."*

From the blowhard antagonist of the Three Little Pigs to the foster mother of Romulus and Remus, wolves have long exercised a powerful hold on human imagination. But in the real-life competition between man and wolf, says zoologist Erik Zimen, the wolf's annihilation seems inevitable. "Zimen focuses his attention on the ecology and behavior of the wolf and offers some new insights about aggression and social ranking...Concerned about survival of the species, Zimen gives some practical advice to conservationists. His descriptions of the pack organization and prey-predator relationships are outstanding."—*Publishers Weekly**

With 16 pages of full-color photographs. $13.95

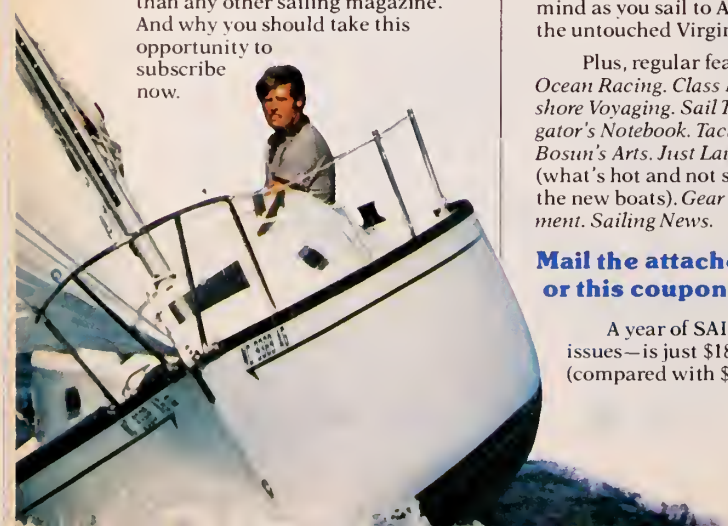
DELL PUBLISHING CO., INC.

SIGN ON WITH SAIL — AND SAVE $6.00 OFF THE NEWSSTAND PRICE

Get a year's subscription, 12 big, colorful, excitement-filled issues for only $18.

No matter what you sail or where you steer her, you'll find more to get excited about in SAIL.



More of the latest seamanship and navigation techniques to help you sharpen your skills.

More of the practical stuff of cruising—both at home and abroad. SAIL's information-packed articles entertain and instruct as they take you to favorite cruising grounds all over North America or to exotic islands abroad.

More firsthand cruising and racing accounts to help you profit from other strategy-wise sailors' experiences.

And more shrewd advice for evaluating new boat and sail designs, equipment, and accessories.

That's why more dedicated sailing enthusiasts read SAIL than any other sailing magazine. And why you should take this opportunity to subscribe now.

SAIL is like getting together with the world's foremost sailing authorities every month

You'll find useful, insightful articles like these in every issue ...with lavish full-color photography that captures the sheer joy of sailing:

FOR SAIL CHEAP
A shrewd look at buying used sails to increase your inventory without sacrificing performance.

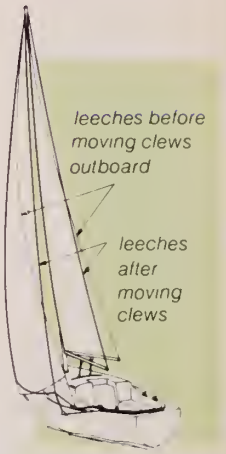
SAILING WITH THE DEVIL'S OWN GRIN
In San Francisco Bay, you can pick your weather, but you may have to sail through a runaway washer cycle to reach your breeze.

CROSSBOW MEETS SLINGSHOT
And the world speed record takes another battering, as two of the wildest design innovations in years face off.

CAPTAIN COMPUTER
Maybe a microprocessor will be getting you back on course in the very, very near future.

HOW MUCH DOES SHE REALLY COST?
Why you should take a flashlight and a mirror to find out whether you're getting a bargain or a bad deal.

CRUISING THE LAST VIRGIN ISLAND
Let the trade wind blow your mind as you sail to Anegada—the untouched Virgin.



Plus, regular features like *Ocean Racing. Class Boats. Offshore Voyaging. Sail Trim. Navigator's Notebook. Tactics. Design. Bosun's Arts. Just Launched* (what's hot and not so hot about the new boats). *Gear and Equipment. Sailing News.*

Mail the attached card or this coupon today.

A year of SAIL—12 monthly issues—is just $18 by subscription (compared with $24 on the newsstand). And you can start your subscription today without sending us a penny. We'll bill you.

GUARANTEE: If you decide at any time that SAIL is not meeting your needs — for any reason — tell us to cancel and we'll send you a refund for any unmailed issues. No questions asked!

That's how confident we are that America's #1 Sailing Magazine is something you won't want to sail without.

Celestial Events

by Thomas D. Nicholson

The Moon Evening skies are dark and moonless at the beginning of February and March since the moon becomes new early in both months: on the 4th of February and on the 6th of March. The moon first appears as an evening crescent on about February 7, grows to first-quarter on the 11th, and becomes full, filling the night sky, on the 18th. Waning thereafter and entering the morning sky, the moon is at last-quarter on February 26 and ends the month as a waning crescent appearing before dawn. The early crescent appears in the evening again on about March 9 and will be first-quarter on March 12. Perigee moon (nearest the earth) is on the 8th of both February and March, apogee (farthest from the earth) on the 24th of both months. The new moon of February 4 eclipses the sun over the South Pacific Ocean, annular in a narrow path crossing the far southern ocean, partial in a much wider area including Australia, New Zealand, South America, and Antarctica.

Stars and Planets Mercury and Mars are poor evening stars in early February, setting early. On the 17th, Mercury moves into the morning sky, leaving Mars as the only planet east of the sun. Venus, Jupiter, and Saturn are morning stars, but Venus rises too late to be seen. Jupiter and Saturn, on the other hand, rise about two hours after sunset, remain in the sky all night, and set after sunrise. Both planets are moving retrograde through Virgo, to the right of its brightest star, Spica. Jupiter, easily the brighter of the two, passes Saturn from left to right on the 19th, the second event in the triple conjunction involving the two planets this year. The first was in January, the third and last will be in July. The two planets will remain close until then.

The sun moves from the stars of Capricornus into Aquarius in mid-February, Mercury leaves Aquarius and shifts to the west (retrograde) into Capricornus, while Venus moves into Capricornus from Sagittarius. There are three planets in Virgo—Jupiter, Saturn, and Pluto. Uranus is in Libra, on the border of Scorpius, and Neptune is in Ophiucus.

February 1: Mercury is at greatest easterly elongation for a week or so before and after this date, placing it in position to be seen as an evening star, low in the west about 45 minutes after sundown.

February 5: The early crescent moon covers Mars (an occultation) today over the Southern Hemisphere. They set too early this evening to be seen.

February 7: Mercury begins retrograde (westerly) motion.

February 10: Mercury and Mars (both setting soon after sundown) are in conjunction. They (like Jupiter and Saturn) also are going through a triple conjunction: the first was in January, this is number two (the "retrograde" conjunction), and the third will be in April.

February 12–13: The star near the moon after sunset is Aldebaran, in Taurus. The moon occults the star before sunset.

February 17: Mercury passes the sun from left to right (inferior conjunction).

February 18–19: Jupiter passes Saturn, the second event in their triple conjunction. Jupiter (the brighter of the two) now moves to Saturn's right, but very slowly.

February 21–22: Be sure to look for the gibbous moon and nearby Jupiter and Saturn, rising about 2½ hours after sundown. The moon passes both planets before sunset, moving slowly away to their left during the night.

March 1: Mercury resumes its direct (easterly) motion as a morning star.

March 4: Mercury is near the waning crescent moon during the early dawn, rising about an hour before sunrise.

March 11: The moon is near Aldebaran again, occulting the star at about 11:00 P.M. EST over northern Canada.

March 15: Mercury, at greatest westerly elongation (to the sun's right), may be seen as a morning star for a week or so before and after this date, but it is quite low in the east even at sunrise.

Mars as seen by the Viking Lander 1 NASA

All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

High Living

by Victor B. Scheffer

ABOVE TIMBERLINE, by Dwight Smith. *Alfred A. Knopf, $13.95; 288 pp., illus.*

It was the kind of assignment many a biologist would jump at. Find a remote place near timberline in a scenic region of the Rockies, a place where you will camp alone from spring to early winter. Set up camera stations from which you will photograph seasonal changes in (1) a pond surrounded by willows, (2) an alpine bog, (3) the edge of a snowfield destined to be bared in summer as a meadow, and (4) a krummholz, or dwarf forest, at timberline. Collect plants and identify them. Record in motion pictures the behavior of high-country birds and mammals. Make friends with the gray jays, nutcrackers, chipmunks, martens, and other camp followers that will visit you.

Plan daily to record your thoughts on tape. Tell what new insights into nature's mysteries you have gained. Describe red dawns, lightning crashing on the peaks, and the soft shapes of new snow. Tell also of changes in your personal outlook on life, for changes will surely steal upon you after months of immersion in a sphere that will seldom echo any human voice but your own. You're apt to learn as much about yourself as about the mountain. Try your best to *enter* your environment . . . but for God's sake be careful!

So Dwight Smith, age fifty, a professor of wildlife management and ecology at Colorado State University, accepted the assignment. He started on snowshoes in June and ended on snowshoes in November. He camped in a deserted gold miner's cabin at an elevation of 11,740 feet, ninety miles southwest of Denver. Enduring painful bouts of bursitis, he cheerfully hiked for miles in the thin alpine air, often carrying a 65-pound pack.

We learn from words that he dictated in the quiet of his cabin that he came from a poor family; worked hard as a farmer, truck driver, mule skinner, logger, and soldier; converted to his wife's religion (Catholicism) twenty-five years after marriage; was 49 before he managed to earn his Ph.D. He's still a workaholic. Although he no longer hunts for sport, he acknowledges the historic contribution made to wildlife conservation by sport hunters and their expenditures.

This book is the fourth in a series conceived by Alan Landsburg Productions of Los Angeles. The idea of the series is "to immerse a biologist in a natural environment for an extended period, alone, far from any laboratory or highway." Three earlier books dealt with an Alaskan lake, a Costa Rican rain forest, and a Pacific atoll.

The setting of the story is one that Zane Grey would have called forbidding—a place of drying winds, intense sunlight and ultraviolet radiation, Saint Elmo's fire, inch-thick hailstones, and avalanches. Living at timberline on the Continental Divide is not easy for Smith. As late as July 24 the ground around his cabin is often covered with frost in the morning, and he feeds two woodstoves in the evening to keep warm. By September 18 summer is over, the thermometer reads six degrees above zero, and Smith is sleeping under seven army blankets. His visits to a doorless outhouse, the seat of which may be white with frost or drifted snow, are as infrequent and swift as possible.

The plants and animals that live at timberline are said by poets to brave the elements, but in fact this is their *place;* they are adapted to it. When, experimentally, they are moved to lower and milder regions, they suffer from competition with native species and from diseases that they have never "learned" genetically to oppose. The only annual plant near Smith's camp is a tiny buckwheat (*Koenigia*). The rest are perennials that bloom quickly in the alpine summer, then pump nutrients into their roots for cold storage during the winter. The champion at survival among the subalpine animals is the pika, a small, rabbitlike creature that cuts hay, dries it in the sun, and caches it under rock slides against the long, dark months ahead.

Now and then I detect educational overtones (not displeasing) in the author's voice—especially when he drifts away from his narrative to reveal some secret of animal behavior.

"The coyote," he explains, "is one of the few large predators to have expanded its range since the advent of civilization." Of the porcupine: "This lumbering creature is one of the most astonishing animals. Any animal willing to carry, lifelong, a prickly armor of some 30,000 barbed quills so that it may peacefully eat tree bark deserves some respect." He reports that a community of gophers can move four to eight tons of soil per acre per year. Of the pikas: "To obtain maximum value from their food [they] regest their own fecal matter, which is high in protein and energy value. They preserve body moisture by depositing almost crystalline urine, which leaves the white nitrogenous salt deposits often seen by hikers here on boulder surfaces." White-tailed ptarmigans, he notes, "are so successful in blending with their environment, and so confident of their invisibility, that it is possible to step on a nesting bird without seeing it."

I'm pleased to read Smith's opinion as to the economic status of pocket gophers on the western range for it happens to coincide with mine. I was studying gophers in Colorado in the 1950s when the "burrow builder" was invented. This is a sort of plow that digs a tunnel (an open invitation to gophers) into which poison baits are subsequently inserted. However, Smith tells us, "there is no conclusive evidence that [gophers] harm our economic interest, let alone the environment in a more general sense."

"What I am suggesting," he continues,

> is that everything in this universe has its place, and every time we diminish or destroy one species we tamper with a complex and delicate system that we know very little about. When the Rolls-Royce company sells an automobile, it comes with a locked hood so the owner won't fool around with the engine. We humans have been given a Rolls-Royce with an unlocked hood and we are tinkering around with machinery we understand poorly.

After a month on the mountain Smith realizes that, constrained as he is by lack of scientific equipment and by lack of free time after working at personal survival, he can hardly do any real research. His mission comes into focus as one simply to produce "a rather human story of a scientifically trained man who lives more or less alone in the wilds for a few months, observing and thinking about the environment he is living in." The result is a book that both educates

For centuries man feared it, made sacrifices to it, wailed over it. Now we run to greet it. You are extended a unique invitation to witness one of nature's most awesome spectacles, a total eclipse of the sun. On July 31, 1981 the British cruise ship, m.s. Coral Princess will be positioned 1000 miles off the coast of Japan to rendezvous with eclipse totality.

The ORIENT ECLIPSE CRUISE and expedition is the sequel to the six previous historic VOYAGE TO DARKNESS eclipse expeditions which successfully intercepted totality off the coasts of Nova Scotia, Africa, the Caribbean, in the Pacific and at Montana's Big Sky eclipse expedition.

The ORIENT ECLIPSE CRUISE adventure offers a distinguished staff of shipboard lecturers (including meteorologist Dr. Edward M. Brooks) scientific, cultural and educational programs, and tours of Japan, Hong Kong, Macau and China.

Join us as we probe earth, sea and space for yet another exciting and memorable cosmic adventure as we sail into totality and beyond.

Light up your life!

CHART ROOM SWIVEL LAMP OF GLEAMING SOLID BRASS

Designed originally for use in ships' chart rooms... now a handsome and handy addition to your home!

Perfect for reading, studying, sewing, crafts, hobbies and all close work

only $64.00 *Sight-Saver Special 2 for $119.00*

This solid brass lamp is a "sight for sore eyes" in two ways. First, its traditional nautical look and efficient design give it a unique, functional beauty that blends well with every decor. Second, and most importantly, it helps eliminate eye-strain with a four-direction swivel feature that puts the light precisely where it's needed. It mounts on the wall, reaches 25" into the dark and can accommodate a high-wattage bulb. Wonderful in any (or every) room of the house... doubly handsome and practical used in pairs to flank a bed or sofa! (Z803585), **$64.00 ea., 2 for $119.00**

OUR GUARANTEE
If you are not completely pleased with your purchase, return it any time for a full, prompt, no-questions-asked refund.

The Evolution of Culture in Animals

John Tyler Bonner

This provocative, fascinating, and delightfully illustrated book traces the origins of culture as we know it back to the early biological evolution of animals.

"... Both lucid and charming.... John Tyler Bonner is a biologist who not only knows a great deal about plants and animals but has thought long and carefully about the problems of evolution.... The pleasure of the book is in the wealth of examples of communication and teaching, many effectively illustrated with drawings or photographs." —*J. Z. Young, London Review of Books.*

52 illus. 9¼ x 6⅛". $14.50

Princeton University Press
Princeton, New Jersey 08540

and entertains. This, I think, is enough.

Smith is visited in August by a Forest Service administrator well versed in land-use planning—a man who is familiar with the uses and abuses of national forests and who values the social, as well as the material, resources of the forests.

"Social resources," he tells Smith, "are resources found in the mind of man." A generation ago, the economic zoning of our national forests was arranged mainly for the benefit of lumbermen, livestock permitees, and mine owners. Today, however, administrators must accommodate users who are interested in recreation, in opportunities for the study of human history and prehistory, in opportunities for natural history research, and in the enjoyment of pure "wilderness" (a word that, in this context, seems to be synonymous with existence value or intrinsic worth).

Smith believes "we are fortunate to have groups such as the Sierra Club, Wilderness Society, and Rocky Mountain Center on Environment that are fighting to preserve wild areas." Strangely, though, he does not belong to either the Sierra Club or Friends of the Earth. The scientists who supply information to these groups are not, he feels, objective. "It has always seemed obvious to me that there is no such thing as a truly unbiased scientist, any more than any other kind of human—and membership in a strong 'advocate' group indicates a strong possibility of bias to me!"

I can't agree. In the real world a person is unlikely to find *any* activist group or political party or religious sect the credo and methods of which he or she can accept unreservedly. Better it is, I think, to join the group—then try gently to bring about the changes within and outside the group one feels are necessary.

Above Timberline can be read as refreshment by anyone. It can be read as education by those who are involved in conserving the green forests and rangelands of the American West. And it can be read as political history by those who study the human exploitation of the natural Earth that allows us life.

Since his retirement from the Fish and Wildlife Service, biologist Victor B. Scheffer has written six books dealing with wild animals. In 1970, The Year of the Whale *was awarded the John Burroughs Medal.*

Sponsor a Child for Only $10 a Month.

At last! Here is a $10 sponsorship program for Americans who are unable to send $15, $16, or $19 a month to help a needy child.

And yet, this is a full sponsorship program because for $10 a month you will receive:

...a photograph of the child you are helping.

...a special sponsorship folder with the case history of the child.

...a description of the country where your child lives.

...a quarterly progress report about your child's community from the field worker.

And you will receive at least two personal letters a year from your child.

All this for only $10 a month?

Yes—because the Holy Land Christian Mission International believes that many Americans would like to help a needy child. And so we searched for ways to reduce the cost—without reducing the help that goes to the child you sponsor.

For example, unlike some of the other organizations, your child does not write each month, but two letters a year from your child keeps you in contact and, of course, you can write to the child just as often as you wish.

Also, to keep down administrative costs, we do not offer the so-called "trial child" that the other organizations mail to prospective sponsors before the sponsors send any money.

We do not feel that it is fair to the child for a sponsor to decide whether or not to help a child based on a child's photograph or the case history.

Every child who comes to Mission International for help is equally needy!

And to minimize overseas costs, our field workers are citizens of the countries where they serve. Many volunteer their time, working directly with families, orphanages, and schools.

You can make a difference!

$10 a month may not seem like much help to many Americans, but to a poor family living on an income of $1.50 or $2.00 a day, your sponsorship can help make all the difference in the world.

Will you sponsor a child? Your $10 a month will help provide so much:

...emergency food, clothing and medical care.

...a chance to attend school.

...help for the child's family and community, with counseling on housing, agriculture, nutrition, and other vital areas to help them become self-sufficient.

A child needs your love!

Here is how you can sponsor a child for only $10 a month immediately:

1. Fill out the coupon and tell us if you want to sponsor a boy or a girl, and check the country of your choice.
2. Or mark the "emergency list" box and we will assign a child to you that most urgently needs to have a sponsor.
3. Send your $10 in right now and this will eliminate the cost of a "trial child."

Then, in just a few days you will receive your child's name, photograph, and case history.

May we hear from you? We believe that our sponsorship program protects the dignity of the child and the family and at the same time provides Americans with a positive and beautiful way to help a needy youngster.

Little Sabina lives with her four brothers and sisters in a little hut on the side of a hill. Her father is dead and her mother tries to make ends meet by selling "tortillas" which she makes by hand each night.

The Edge of Sight

Human beings, always looking for ways to push back the limits of their senses, have long been dissatisfied with the resolving power of the human eye. The Romans used water droplets and glass to magnify things, but it wasn't until the fifteenth century that the eye's limitations were overcome.

Historians believe that the first microscope, a simple glass magnifier, was invented sometime about 1450 by an unknown entomologist as an aid in drawing insects. As Anton van Leeuwenhoek, Hans Jansen, and others built better microscopes, a strange new world populated by bizarre one-celled animals and tiny plants gradually unfolded. Much later, scientists began to explore the structures inside the cells—mitochondria, Golgi bodies, and the endoplasmic reticulum.

The limitations of light itself, not the human mind, ultimately halted the steady improvement of the light microscope: the wavelength of visible light is simply too long to pick up small details, no matter how powerful the lens. In 1924 a physicist suggested that electrons bounced off a specimen would magnify better than light since the wavelength of electrons is thousands of times shorter. Shortly afterward, a microscope that used electrons was built, and the limits of resolution were again pushed back.

The American Museum of Natural History bought its first electron microscope, a Cambridge S4-10, in 1972 for $90,000. At the time it was one of the best microscopes in the world. But such is the progress of technology that today the S4-10 is considered obsolete, bulky, and inefficient.

This month, technicians in the Museum's Interdepartmental Laboratory will unplug and unscrew the S4-10 and trade it in—plus $120,000—for a brand-new microscope: a Cambridge Stereoscan 250. Most of the funds were provided by a grant from the National Science Foundation obtained by curators Roger Batten and Bruce Haugh, with the help of Robert Koestler, who manages the laboratory. The new scope, of which only ten have been built so far, is one of the finest of its kind. "It's a second-generation instrument," says Koestler. "Everything has been done over."

Like the old scope, the 250 is a scanning electron microscope, or SEM, which produces a three-dimensional picture by bombarding a specimen with a shower of electrons. The electrons are shot down in an evacuated column toward the specimen. Magnetic fields along the column, acting as lenses, focus the electrons into a narrow beam. The beam scans rapidly across the specimen line after line, much like reading a book, and a black-and-white image of the surface of the specimen appears on a television screen. Because electrons, unlike light, have no color, SEM pictures are always black and white.

Electron microscopes in general are much more powerful than light microscopes. The most powerful light microscope can magnify 2,000 times, while the new SEM can magnify up to 570,000 times. To give an example, under a light microscope, the point of a pin looks surprisingly blunt. Under the SEM, however, a pinpoint becomes an entire landscape.

The Museum's new SEM provides an array of fancy electronics that the old one lacked. The banks of vacuum tubes have been replaced by solid-state electronics, a minicomputer automatically adjusts the electron beam for greatest depth of field, and a new 4- by 2-inch specimen chamber will allow Museum scientists to look at specimens that were too large to fit into the old ½-inch chamber. The 250 has twice the resolving power of the old S4-10, eight times the depth of field, and three times the magnification. Even more important for the Museum's research, it can also achieve very low magnifications—about the same as a pair of thick eyeglasses—to look at large specimens. In addition, the Stereoscan 250 offers such options as an "energy dispersive system," "solid-state backscattering analysis," "cathodoluminescence," and "X-ray nucleonics."

The new machine will be used to analyze everything from diamonds and fossilized sea urchins to spider genitals. Koestler estimates that one hundred curators and research associates will use the SEM for their research projects. David Hurst Thomas, chairman of the Department of Anthropology, is studying tool assemblages from an archeological site in Nevada. His results will appear in a 2,000-page Museum monograph on the archeology of the entire Great Basin area. Thomas used the old machine to look at the microscopic wear pat-

The Hopi

A new exhibition at the Museum, *Hopi Kachina: Spirit of Life*, will open February 9 in Gallery 3. The exhibition focuses on the annual kachina ceremonies of the Hopi, one of North America's oldest continuous cultures. Models of Hopi villages, scenes of the cult ceremonies, kachinas, and other Hopi artifacts will be on display. *Hopi Kachina* was organized by the California Academy of Sciences.

Black History

The Museum's African-American Program will observe *Black History Month* with a number of events celebrating the cultural richness and diversity of African and African-American peoples. The programs will be presented in the People Center on four weekends, beginning Sunday, February 1; among them are *Music and Folk Traditions of East Africa, African Toys and Games*, and *African-American Cooking*. Films on related subjects will also be shown during the weekends. All programs are free and will take place throughout the afternoon from 1:00 to 4:30. Other programs commemorating Black History Month—including a multimedia tribute to singer/actor/activist Paul Robeson on Sunday, February 21, at

terns on ancient tools to find out how they were used. But the specimen chamber on the old machine was too small to accommodate most tools, and thus the SEM was only used as a supplement to the light microscope. The larger specimen chamber of the new scope will allow Thomas to do broader, more thorough research.

George Harlow, a curator in the Department of Mineral Sciences, will use the Stereoscan 250 to investigate the structure of asbestos fiber, which is too fine to be seen with the light microscope. Among Harlow's concerns are those properties of asbestos that might induce biological activity. He says, "The more we understand the structure of asbestos and other powdered minerals, the more we will know why such minerals can cause various diseases, including cancer."

Roger Batten, who was the prime mover in getting the old scope, will use the new one for his research on fossil bivalve mollusks. His research is adding to our knowledge of earth history and evolution and, incidentally, providing valuable information for oil exploration. Bruce Haugh is also working on a complex evolutionary problem involving the fossilized microanatomy of echinoderms (sea urchins, starfish). His findings are challenging traditional views of echinoderm evolution.

Other Museum projects that will benefit from the 250 range from a study of feathers to aid in the classification of birds to documentation of mineral localities in New Jersey.

During its lifetime, the S4-10 served the Museum well. It provided thousands of photographs for more than eighty scientific publications and extended the systematic research of the Museum into new areas. As an even more powerful extension of our ability to see, the Stereoscan 250 will add to our understanding of nature.

Douglas J. Preston

2:30 P.M.—will be held in the Education Hall and the Auditorium.

Evening Courses

February marks the beginning of the Education Department's Spring Evening Lecture Series. Over the years, these popular lectures have brought the world of natural history, anthropology, and geology to thousands of interested people.

Studying Birds is a four-evening series that will cover High Andean Birds, Endangered Cranes, Birds of the Amazon and Meadowlarks. Various authorities on birds, including Thomas Lovejoy of the World Wildlife Fund and François Vuilleumier of the Museum's Ornithology Department, will present each lecture. Tuition is $20.

Symbol and Shadow will explore the world of Asian puppetry, using the Museum's extensive puppet collection. Included in this series of five lecture-performances will be Cambodian puppetry and music, the development of shadow theater in China, and a performance of Bali puppets collected by the late Margaret Mead. Tuition is $30.

The Hopi, a six-lecture series, complements the special Museum exhibition Hopi Kachina: Spirit of Life. The illustrated lectures will cover, among other topics, the 1,000-year prehistory of the Hopi, the kachina cult, the Snake Dances, and the fifteenth-century Awatovi murals. Tuition is $30.

Other lecture series are *Anthropology Through Films*, *The World of Islam*, *Mammals of North America*, *Plant Life at the Edge of the Sea*, *Foraging for Dinner*, *Animal Drawing*, *Insects*, and *Explore Weaving*. Write to the Education Department for a brochure and preregistration form.

Junior Natural History

The Education Department is offering four *Workshops for Young People* beginning in February: Exploring with the Microscope, Photographing People, The Arts of Asia, and Games People Play. The workshops add a special dimension to the Museum learning experience for children in grades 4 to 7. Each workshop lasts six weeks, and tuition is $20. Write to the Education Department for details.

Inner Landscape

On Wednesday, February 11, at 7:00 P.M. in the Auditorium, the Education Department and the Society for the Study of Myth and Tradition are presenting *Sacred Geography: An Inner Vision of Ecology*. Free illustrated lectures will explore Native American views of the universe as expressed through myths, stories, afterworld beliefs, and ceremonies.

Films for the Family

On Washington's Birthday (Monday, February 16) a Family Film Festival will be shown in the Auditorium at 1:00 and 3:00 P.M. The free films are especially presented for families visiting the Museum on the holiday.

Cosmic Visions

The February membership program will be *Visions at T Minus Zero*, presented by John Teton. *Visions* incorporates film shorts, including excerpts from science fiction thrillers, cartoons, and NASA clips, into a program about astronomy, cosmology, and the universe. Astronomer Robert Chambers says about *Visions*: "The impact of *Visions* on its audience is tremendous. . . . Teton built a mechanism that got through to people as few things have." The program is free for members, $3.50 for nonmembers, and will be shown on Wednesday, February 25, at 7:30 P.M. in the Auditorium. *Visions* will be repeated on Sunday, March 1, at 2:00 P.M. in the Auditorium.

Additional Reading

Hutterites (p. 34)

According to the *New York Times Book Review,* J. A. Hostetler's *Hutterite Society* (Baltimore: The Johns Hopkins University Press, 1976) is "the definitive history and ethnography of the Hutterites." *All Things Common*, by V. Peters (Minneapolis: University of Minnesota Press, 1965), is a well-written, general study of the Hutterites. J.W. Bennett's *Northern Plainsmen* (Chicago: Aldine Atherton, 1969) is an economic, anthropological study of the different agrarian and adaptive strategies used by Hutterites, Indians, and farmers in the Jasper, Canada, region, while his *Hutterian Brethren* (Stanford: Stanford University Press, 1967) offers insights into the agricultural economy and social organization of the Hutterites of southwestern Saskatchewan. *The Hutterites in North America*, by J.A. Hostetler and G.E. Huntington (New York: Holt, Rinehart and Winston, 1967), is a detailed description of Hutterite daily life. For an insider's perspective, see *The Hutterite Way*, a work written by a Hutterite, P.S. Gross (Saskatoon: Freeman Publishing Co., 1965), which covers the life, customs, traditions, and religion of the Hutterites. The classic history of the Hutterites is J. Horsch's *The Hutterite Brethren 1528–1931* (Goshen: Mennonite Historical Society, 1931). D. Flint's *The Hutterites* (Toronto: Oxford University Press, 1975) examines Hutterite daily life and beliefs, particularly as demonstrated in a Pincher Creek, Alberta, colony. J.A. Hostetler gives the most detailed account of Hutterite child-rearing practices in "Communal Socialization Patterns in Hutterite Society (*Ethnology*, October 1968, pp. 331–55). "The Christian Communists of Canada" (*GEO Magazine*, November 1979, pp. 126–54), which features many color photographs, is M. Holzach's recounting of his experiences living in a Hutterite colony in Canada. An anthropological case study of a related Anabaptist sect, J.A. Hostetler and G.E. Huntington's *Children in Amish Society* (New York: Holt, Rinehart and Winston, 1971) discusses Amish child training and schooling. "The Anabaptist Explosion," by W.F. Pratt (*Natural History*, February 1969, pp. 8–23) explores the traditionally high levels of fertility among the Hutterites and Amish.

Walrus (p. 48)

A systematic account of the pinnipeds, V.B. Scheffer's *Seals, Sea Lions, and Walruses* (Stanford: Stanford University Press, 1958) examines the distribution and variation patterns of these animals. *Diving Companions*, by J.Y. Cousteau and P. Diolé, translated from the French by J.F. Bernard (New York: Doubleday and Co., 1974), recounts the experiences of the *Calypso* crew while witnessing the springtime migration of the walrus in the Arctic. R. Perry's portrait of walrus life and society, *The World of the Walrus* (New York: Taplinger Publishing Co., 1967), discusses human exploitation of the walrus. For detailed descriptions of all seal species, consult G. Maxwell's *Seals of the World* (Boston: Houghton Mifflin, 1967). A popular work treating the yearly rhythms of arctic animals, *The Arctic Year*, by P. Freuchen and F. Salomonsen (New York: G.P. Putnam Sons, 1958), gives extensive coverage to the walrus. The May/June 1980 issue of *Oceans* features a photo essay, "The Pinniped Papers" (pp. 11–17) and two articles by D. Haley: "Tooth-Walking Sea Horse" (pp. 38–44), which provides general information on the walrus, and "Future of the Walrus: Rise Before the Fall?" (pp. 62–63), which explores how discovery of oil and minerals in the Bering and Chukchi seas may affect the area's walrus population. B. Keating's *Alaska* (Washington, D.C.: National Geographic Society, 1971) offers a section on the Diomede Islands. Two recent *Natural History* articles dealing with the walrus, with text and photographs by F. Bruemmer, are "The Gregarious but Contentious Walrus" (November 1977, pp. 52–61) and "Life on a Cold Rock" (March 1977, pp. 54–65).

Acid Rain (p. 58)

The first article in a two-part series on acid rain by S. West in *Science News*, "Acid from Heaven" (February 2, 1980, pp. 76–78), deals with the sources of acid rain; the second, "Acid Solutions," (February 16, 1980, pp. 106–108) looks at the scientific and political problems involved in controlling it. *Environment* published a series of articles investigating acid precipitation: "Acid Precipitation: 1. Causes and Consequences," by H. Babich, D.L. Davis, and G. Stotzky, appeared in the May 1980 issue (pp. 6–13); the June 1980 issue featured G.S. Wetstone's "The Need for a Regulatory Approach" (p. 9), A. Rosencranz's "The Problem of Transboundary Pollution" (p. 15), and Wetstone and Rosencranz on "National and International Responses" (pp. 6–7). "Acid Rain," by G.E. Likens et al. (*Scientific American*, October 1979, pp. 42–51), includes many maps and diagrams charting the rise in acid rain from the mid-1950s to the mid-1970s. In "Acid Precipitation in the Western United States" (*Science*, January 11, 1980, pp. 176–77), W.M. Lewis and M.C. Grant associate the downward trend in pH levels of the last three years with the increase of nitric acid in precipitation. *Acid Rain* (Washington, D.C.: EPA Office of Research and Development, July 1980), a 36-page exploration of acid rain, covers the laws that govern the emissions resulting in acid rain and the research now under way to understand its implications and effects. This publication costs $3.25 and can be ordered by writing to Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402 and requesting GPO-055-00-00198-7. *Sulfur in the Environment*, edited by J.O. Nriagu (New York: John Wiley and Sons, 1978), is a two-volume compendium of articles focusing on the behavior and effects of sulfur and the ecological stress created by this pollutant. Other books containing technical material on acid rain are: *Effects of Acid Precipitation on Terrestrial Ecosystems*, edited by T.C. Hutchinson and M. Havas (New York: Planum Press, 1978); *Atmospheric Sulfur Deposition*, edited by D.S. Schreiner, C.R. Richmond, and S.E. Lindberg (Ann Arbor: Ann Arbor Science, 1980); and *Polluted Rain*, edited by T.Y. Toribara, M.W. Miller, and P.E. Moro (New York: Planum Press, 1980). A number of articles by G. Hendrey, on the effects of acid rain

on the aquatic environment, are available from him at Brookhaven National Laboratory, Upton, New York 11973. Papers from the Norwegian project on "Effects of Acid Precipitation on Forest and Fish" can now be obtained by writing to SNSF, 1432 Aas-NHL, Norway. The 315-page *Proceedings of the Action Seminar on Acid Precipitation November 1–3, 1979* (Toronto: ASAP Coordinating Committee, 1980), a less-technical compendium of the papers given at this symposium, is available for $6.50 (Canadian) from the Federation of Ontario Naturalists, 355 Lesmill Road, Don Mills, Ontario, M3B 2W8, Canada.

Wolves (p. 66)

E. Zimen's *The Wolf*, translated by E. Mosbacher (New York: Delacorte Press, 1980), from which the article in this issue is adapted, focuses on wolf ecology and behavior and provides the most thorough coverage of Abruzzi wolves. *The Behavior and Ecology of Wolves*, edited by E. Klinghammer (New York: Garland Publishing, Inc., 1979), is a series of articles exploring the reintroduction of the wolf into the wilds. Organized into five sections—wolves in the wild, analysis of behavior, translocation and reintroduction, wolves in captivity, and the red wolf—this work includes data on Abruzzi wolves. L. D. Mech's *The Wolf* (Garden City: Natural History Press, 1970) is a readable, well-documented, standard text on wolves. M.W. Fox's *Behaviour of Wolves, Dogs, and Related Canids* (New York: Harper and Row, 1971) is an account of the social organization and behavior of some canids and includes a large, illustrated section on the wolf. B.H. Lopez's *Of Wolves and Men* (New York: Charles Scribner's Sons, 1978), a folkloric essay on the wolf, is enriched by a descriptive bibliography.

Rita Campon

Errata: In our December issue the photograph of goldenrod on page 42 was incorrectly identified as ragweed. On page 44, the text should read "destroyed millions of square acres," not "square miles." And on page 58, "one century later," should read "one millennium later."

This course (*specifically designed by the U.S. Department of State for Diplomats with little or absolutely no knowledge of the language to be studied*) is **complete**, **unedited** and includes the official Foreign Service Institute book with text for basic and advanced instruction. It begins in English and will gradually build your skills until you can comfortably handle the entire lesson in your new language. In a matter of weeks, you could be speaking your new language like a member of the U.S. Foreign Service Corps.

ONE LOW PRICE FOR YOU...ALL OTHERS LEARN FREE!

What an incredible value! For the single purchase price of one course your whole family can learn a new language and keep the course for years of fun and future reference.

The *complete* full length Foreign Service Language Course is now being offered in two volumes:

VOL. 1, BASIC SPANISH 15 cassettes (19 hours) and 464 pg. Foreign Service Institute text **$99.95**

VOL. 2, ADVANCED SPANISH 21 cassettes (27 hours) and 464 pg. Foreign Service Institute text **$89.95** (The number of cassettes in FRENCH, GERMAN and ITALIAN Courses vary slightly from the SPANISH Course.)

FREE TRIAL OFFER. Try this course for three weeks. If you aren't convinced it's the fastest, easiest, most economical way to learn a new language, return the course for a full refund with no questions asked. Order yours right now!

For immediate delivery, fill in the information on the bottom of this ad and mail it with your check, Money Order or charge to your AmEx, Visa or Master Card by enclosing card number, expiration date and signature.

LEARN SPANISH, FRENCH, ITALIAN OR GERMAN LIKE A MEMBER OF THE U.S. FOREIGN SERVICE CORPS.

(each course is less than $100!)

Satisfaction guaranteed or your money back. AN IDEAL GIFT!

SPECIAL INTRODUCTORY OFFER!

Order both BASIC and ADVANCED Course in any language and take advantage of a full 10% discount! **Mail to: AMPRO PRODUCTIONS** 150 Fifth Avenue, New York, NY 10011.

NOW you can order by phone 24 hours a day! Call collect (9AM - 6PM EST) **(212) 243-7726**

N.J., N.Y., CT., residents can also buy direct at our Fifth Avenue office (at 20th Street)

Fill in the line below with the language you wish to learn...then check basic, advanced or both.

Jack Daniel Square Coaster Set

Every once in a while, something comes along which is so simple and direct that I wonder why I didn't think of it myself. Well, even though I didn't think of these, someone at the distillery decided to have a square drink coaster to match the square glass. Pretty clever, huh?

Anyway these six coasters are redesigns of old Jack Daniel advertising art and are full color. Each is different and measures 4⅛" square. They are cork backed and impervious to alcoholic beverages. My **$10.00** price includes postage.

P.S. But I wonder, if they're so smart, why did they make six coasters for only 4 glasses?

Send check, money order or use American Express, Visa or Master Charge, including all numbers and signature. (Tennessee residents add 6% sales tax.)

For a catalog full of old Tennessee items and Jack Daniel's memorabilia, send $1.00 to the above address. Telephone: 615-759-7184

Forbidding Fruit

If eaten before perfectly ripe, the persimmon can be a mouth-puckering experience

by Raymond Sokolov

The only reason anyone without a flat tire stops in Gnaw Bone, Indiana, is to visit the Brown County Sorghum Mill. It isn't really a mill, just a big farm stand on a highway in southern Indiana. It opens for business only during the fall harvest season and sells the typical crops of Brown County's rolling, picturesque farm country: pumpkins, apples, twists of bittersweet, sorghum molasses, apple butter. The mill did not have any of the big goose-necked gourds or the strawberry popcorn, grown on tiny dark red ears, that I had bought at another stand just north of Nashville, a tourist center and artist's colony that makes a big business out of Indiana's log cabin era, with one hokey olde-time shoppe after another flogging folksy crafts and souvenirs. Gnaw Bone has its own specialties.

At the Brown County Sorghum Mill, only three miles or so from Nashville, Nancy Roberts preserves Midwestern homestead tradition without cuteness or hoopla. She makes fudge and candy and a cakelike "pudding" from the fruit of the native persimmon tree. Well, some days she does. But Mrs. Roberts also drives the Gnaw Bone school bus, and she has trouble getting persimmons, which are a tiny and tastier cousin of the Asian variety sold in supermarkets. Her usual supplier, busy with a new job in Indianapolis, hadn't delivered any pulp last fall when I happened by.

"Pulp?" I asked, inwardly cursing Jane and Michael Stern, whose excellent guide to American highway restaurants, *Roadfood*, had led me to this remote hamlet with visions of native persimmons dancing in my head. Instead, there was nary a piece of fudge, just talk of a pulp scarcity.

"She used to process the fruit from her orchard, get rid of the skins and seeds, and sell me the pulp," Mrs. Roberts said. But the supplier wasn't home. Mrs. Roberts didn't know where or on which back road she lived. At any rate, if I came back the next day, Mrs. Roberts would have a batch of persimmon fudge she was going to cook that night from some of last year's pulp still left in her freezer.

I took another tack. I checked the main supermarket in Nashville. No persimmons, at the height of the season. Next, I dropped in at the local office of the U.S. Department of Agriculture's Cooperative Extension Service. The woman behind the counter said there were no proper persimmon orchards in the county. Nobody cultivated persimmons. They just grew wild: in open places, clearings, abandoned fields. You waited until after the first frost and then picked them up off the ground where they fell. Fruit still on the tree was too astringent to eat. The fall had been so mild that the persimmons might not be ready yet. She told me to go look at a tree in her mother-in-law's yard at the edge of town.

An understandably suspicious older woman greeted me and pointed out her tree—slender, fifty feet high, with dark bark deeply divided into squarish sections. Up in the leafless branches I saw tiny orange fruits. The woman's relatives had gathered all the fallen fruit the day before, and the ground under the tree was bare.

At the post office, I got directions to the house of Mrs. Roberts's supplier, the woman with the "orchard." An hour later, after losing my way in a delightful labyrinth of tree-lined lanes, I pulled up to a desolate mobile home set behind a half-built house in the early stages of dilapidation. Stepping out of the car, I was attacked by a small mongrel, a dingy beige bitch who took a bite of my left ankle and would have taken a second helping if another, larger but better-behaved cur had not chased her away. Expecting the report of a shotgun, I waited a minute or two by the car. But no Jukes or Kallikak emerged from the battered trailer, so I limped across the field toward a scraggly stand of trees. A few feet from them, I slipped on what felt like a spot of mud. It was red orange and had three large black seeds. In the branches overhead, hundreds of similar persimmons dangled. And in the brown grass, strewn in every direction, were squishy-squashy ripe persimmons waiting to be saved from their natural predators: squirrels, opossums, skunks, quails, raccoons, and deer.

Having liberated as many fruits as I could gather in my shirt, I retired to the safety of my vehicle. They were definitely the fruit of *Diospyros virginiana*, the American persimmon. Small, about the size of walnuts or cherry tomatoes, they resembled the much larger, heart-shaped oriental persimmon (*Diospyros kaki*) only in color and in the gooey texture of their inner flesh. In flavor, these American persimmons far surpass their imported cousins. They are powerfully fragrant,

Adelaide de Menil

The American persimmon (Diospyros virginiana)

sweet and luscious, and taste like dates. Indeed, one of their vernacular names is date plum. They are wonderful fruits.

Early settlers realized this almost immediately upon their arrival in America. DeSoto wrote the first description of the persimmon in 1539 in Florida. The name itself apparently derives from the Algonquin *putchamin* or *pasiminan*, meaning "dried fruit." Well into the colonial era (and perhaps still) dried persimmons were stored and eaten like figs. Colonists must also have learned from Indians that the little fruit lent itself to baking in breads, cakes, and puddings. And we can be sure the Pilgrims had the good sense to consume persimmons out of hand, knowing from bitter experience that they had to wait for this treat until the natural ripening process had masked the fruit's tannin and made it sweet. As Capt. John Smith put it: "If it not be ripe, it will drawe a man's mouth awrie with much torment; but when it is ripe, it is as delicious as an Apricock."

Easily grown from seed, the persimmon was established in English gardens before 1629 and was introduced into Europe in the early eighteenth century, where it can still be found, but sun-starved American persimmons in the Old World rarely reach a height of more than thirty feet. On native ground, persimmons do much better, normally topping out at something under fifty feet.

D. virginiana is a member of the Ebenaceae family, but unlike almost all the other ebonies, it is not tropical. Its range extends across the United States from Florida and Texas into New England. Particularly valued for its timber, this hardwood has been characteristically employed for shoe lasts, weaver's shuttles, and golf club heads. The dark heartwood takes a century to develop, but then it surpasses in hardness any native wood except ironwood and dogwood.

Small flowers bloom in early June and typically evolve into ripe fruit by October. Contrary to persistent folklore, frost has nothing to do with the ripening process. Indeed, the notion that a hard frost was required before the fruit would lose its tannic, mouth-puckering astringency has probably kept the native persimmon from achieving popularity as a commercial fruit. Everyone I met in Indiana told me that frost was essential, and that I should only attempt to eat fruit that had fallen on the ground. Unimpeachable botanical authority asserts that this is false, that fruit with a good, dark orange color should be picked while still solid (cut rather than pulled from the stem), and that it can be ripened fully, until it is very soft, off the tree. I tested this proposition with several firm fruits, and it is so. Furthermore, ripening can be hastened along by bagging persimmons together with an apple.

In other words, there is no reason to wait until persimmons have fallen to the ground from their own heaviness and gone smash. A commercial grower could easily harvest a crop while it was still firm enough to travel and get it to market in good shape. Off-tree ripening, by the evidence of my own experiment, produces just as flavorful a fruit as the benign neglect preached by tradition.

Other factors besides the frost legend have also worked against popular acceptance of the persimmon. The fruit is small. Most varieties have several seeds. Indeed, the seeds are such a prominent feature of the fruit that a woman in Bloomington, Indiana, told me there was a local tradition of using them to divine the severity of the approaching winter.

Seeds, tannin, and frost legend notwithstanding, it has been obvious to everyone who ever tried a ripe persimmon that it was a fruit of enormous appeal and sophistication worth commercial exploitation. At the end of the nineteenth century and the beginning of the twentieth, nurserymen developed various cultivated varieties: some early blooming, one virtually seedless. But a market never materialized. City people didn't want native persimmons. But the cultivars are still available.

Those interested in planting a persimmon tree should write Gerardi Nursery, Route 1, O'Fallon, Illinois 62269 or California Nursery Company, Box 2278, Fremont, California 94336 or Waynesboro Nurseries, Waynesboro, West Virginia 22980. Do not try to transplant a wild tree without professional assistance, as the extremely deep taproot makes this a very dicey project. I met a man in Brown County who had failed on several tries. He at least had several other trees that bore fruit almost at his doorstep. And almost no one was competing with him for their bounty.

Only the initiated seem to bother with wild persimmons, which are either out of reach, overly tannic, or lying squashed or unappealingly flaccid on the ground. I was able to glean another shirtful at the edge of a recreational vehicle parking lot in Brown County State Park. Vacationers sitting on vinyl folding chairs eyed me with disdain as I gathered persimmons from a nearby grassy knoll littered with fruit and the paper debris of human tourism.

Some of those same rusticating urbanites must have driven home and found bigger but not nearly as interesting heart-shaped oriental persim-

The 80 proof drink with a taste you don't have to acquire.

COINTREAU LIQUEUR, 80 PROOF. RENFIELD IMPORTERS, LTD., NY ©COINTREAU CORP., 1980.

mons in their markets for fifty cents apiece. In recent years, *Diospyros kaki* has established a foothold in U.S. groceries as a specialty fruit. With a long history as a cultivated plant in Asia (especially in Japan, where it is more popular than all other fruits except citrus and amounts to the national fruit), the *kaki* persimmon has been astutely marketed.

Meanwhile, the native fruit, clearly superior, remains misunderstood and neglected. Country people who value it gather it in the same spirit of woodland foraging that they approach wild mushrooms. And they have preserved the dozens of recipes developed for *D. virginiana* in earlier times. Bear Wallow Books (P.O. Box 579, Nashville, Indiana 47448) publishes a cookbook completely devoted to the various persimmon cakes, puddings, breads, cookies, pies, salads, ice creams, and candies that Hoosiers have traditionally prepared.

Early settlers in Pennsylvania made persimmon wine. In Virginia and Maryland, they distilled persimmon brandy. As a girl in Freetown, Virginia, Edna Lewis helped to make persimmon beer. In *The Taste of Country Cooking*, she recalls:

> We would pick over all that we had gathered and then stir them into a medium-soft batter made from the bran of white cornmeal mixed with spring water. After it was all well mixed, we would spoon the batter into a large bread pan and bake it in the oven. After it had baked and cooled, the cake was placed in a stone crock or a wooden keg with twice as much spring water, then covered and left to ferment until Grandfather decided it was ready for drinking—usually in late winter.

"Simmon" beer will never replace Schlitz. And the American persimmon will probably never supplant the oriental persimmon in American markets. *D. kaki* has an even bigger head start over its native rival than Honda has over Chrysler's K cars. But even Hirohito would probably agree that our persimmon is better than his. This isn't chauvinism, but fact. Anyone who needs further convincing can just head for Gnaw Bone in the fall. If Mrs. Roberts doesn't have any fudge (which is delicious and worth waiting a day for), just find a tree and start eating.

Raymond Sokolov is a free-lance writer whose special interest is the history and preparation of food.

Adelaide de Menil

Bear Wallow Persimmon Pudding

1 egg, lightly beaten
2 cups persimmon pulp (made by pushing ripe fruit through a colander)
3/4 cup sugar
3 cups milk
2 cups sifted flour
1/2 teaspoon baking soda
1 tablespoon butter, cut in small slivers
1/4 teaspoon salt
1/2 teaspoon vanilla

1. Preheat the oven to 350 degrees.
2. Stir the egg into the pulp. Then stir in the sugar.
3. Next, stir in the milk and flour, alternating between the two, adding a half cup or so at a time. Beat well.
4. Dissolve the baking soda in a teaspoon of hot water and beat it into the persimmon mixture. Then beat in butter.
5. Pour into a greased 9 by 13 baking pan. Bake for 1 to 1½ hours, or until dark in color. Four or five times during baking, stir mixture so that it will not harden at edges of pan. (Remove pudding from oven each time so as not to lose oven heat during stirring.)

Yield: 8 to 10 servings

Jeffrey Steingarten's Persimmon Ice Cream

1 cup milk
3/4 cup sugar
Juice of 1 large lemon
1¼–1½ cups persimmon pulp
2 cups heavy cream (avoid ultra pasteurized cream if at all possible)

1. Scald milk. Stir in sugar until dissolved. Cool to room temperature.
2. Stir lemon juice and pulp into milk mixture. Then stir in cream. Correct taste if necessary by adding more lemon juice.
3. Chill 8 to 10 hours or overnight, if possible.
4. Freeze in an ice cream freezer.

Yield: 5 to 6 cups

World praise for the new World Car

"...almost a dream car..."
EXPRESSEN, SWEDEN

"...Ford's cam-in-head (engine) can produce both economy and...energy."
CAR & DRIVER, USA

"The most advanced technical characteristics Ford has ever produced."
AUTO SPRINT, ITALY

"This destiny car is marvelous all around..."
BILD ZEITUNG, GERMANY

"Economical, fuel-and-space efficient... entertaining to drive..."
ROAD & TRACK, USA

"Road Test magazine's Car of the Year!"
ROAD TEST, USA

Ford engineers all around the world worked together to build a technologically advanced, economical automobile—Ford Escort, the new World Car.

44 EST HWY* (30) EPA EST MPG*

*Applies only to sedans without power steering or A/C. For comparisan. Your mileage may differ depending on speed, distance, weather. Actuol hwy mileage ond Colif. rotings lower. Excludes diesels.

Now, both the American and the overseas versions are winning accolades from automotive experts in their countries.

And no wonder. The compact Escort has front-wheel drive, a new-design hemispherical head engine, 4-wheel independent suspension, and better gas mileage ratings than subcompacts like VW Rabbit, Honda Accord, Toyota Corolla Hatchback.

See it at your Ford dealers.

Built to take on the world... and doing it!

hexa·photo·cybernetic
The Possibilities are Endless.

Stopped-Down:

Six-mode exposure control. System versatility. Newer electronics for wider applications.

The Canon A-1 is one of the world's most advanced automatic SLR cameras. Combining the finest in optical and mechanical engineering with the most sophisticated electronics, it's technology applied to give you the ultimate in creative control. At the touch of a button.

Depending on your subject, you can choose from six independent exposure modes to achieve the results you want:

1 Shutter-Priority: You select the shutter speed, to freeze the action and prevent camera shake or create an intentional blur. The A-1 automatically selects the appropriate lens opening.

2 Aperture-Priority: Control the area in focus by selecting the lens opening for the effect you want. The A-1 matches with the right speed.

3 Programmed: When you need to shoot fast, just focus. The A-1 will select *both speed and aperture* for great results.

4 Stopped-Down: For extreme close-up or specialized photography, a bellows, a microscope or almost anything can be attached to the A-1. It's still automatic.

5 Flash: Totally automatic flash photography, of course, with a wide variety of Canon Speedlites to choose from.

6 Manual: Yes. For those times when you absolutely want to do it all yourself. To experiment. To explore the possibilities.

There are over forty fine Canon lenses ranging from Fish Eye to Super Telephoto, plus accessories to meet every need. If you can't photograph your subject with a Canon A-1, it probably can't be photographed.

From the sophistication of its LED viewfinder display, to a ruggedness that allows up to five-frame-per-second motor drive, the Canon A-1 represents an incredible technology. At a price that makes owning one a definite possibility.

Last Chance to Buy at These Low Prices

This is the FINAL OFFER at these LOW PRICES. Inflationary pressures require a moderate price increase effective May 31, 1981. However, those who enter a new subscription before that date will be guaranteed price protection at current prices for the first two full years of enrollment. Act immediately to beat the scheduled price increase, and be eligible to continue to buy these luxurious volumes at today's low prices well into 1983.

The Luxury Of Full Leather Bindings

Do not confuse these masterful editions with other volumes which feature partial leather bindings on the spine only.

There is no comparison! Every book in this collection is fully bound in genuine leather. Once you have experienced owning editions of such superlative quality, you will fully appreciate the extraordinary difference.

The 100 Greatest Books Ever Written

The world's greatest works of literature bound in genuine leather and accented with real 22kt gold.

It is not difficult to list the world's greatest books. The titles and authors leap quickly to mind. And for good reason. The books that have been recognized as great, generation after generation, are part of the world we live in. They have shaped our lives, our language, our values, our outlook.

These books include novels like Melville's *Moby Dick,* Dickens' *A Tale of Two Cities,* Hawthorne's *Scarlet Letter,* Bronte's *Wuthering Heights.* They include serious—yet highly readable—works of thought like Plato's *Republic*...heroic epics like Homer's *Iliad*...sharp-witted satire like Swift's *Gulliver's Travels*...brilliant poetry like Whitman's *Leaves of Grass.*

On everyone's list would be the great works of Shakespeare, Chaucer, Dante, Darwin, and Twain. These are books you want on your bookshelf. Books you want your children and their children to read. And now you can have them—the ultimate private library.

The Volumes Themselves are Works of Art

Your pride in this collection will be twofold—arising both from the significance and stature of each literary masterpiece ...and from the sheer beauty of each volume. Every volume in this unique private library will exemplify the ultimate in the art of printing, binding, and illustration.

Genuine Leather Bindings

Today it is rare to find books bound in genuine leather. The cost of such bindings and the time required to create them has made the crafting of such bindings an almost vanishing art. **But each book in this collection will be bound in genuine leather!**

Intricate Cover Designs Accented With Real 22kt Gold

Each luxurious leather binding will be deeply inlaid with real gold on the spine and in perfectly-matched golden designs on the front and back covers. Then, to bring out the full beauty of each cover design, the pages will be gilded along all three sides with a special golden finish.

Elegant Finishing Touches

Each volume will have beautiful endsheets of rich moiré fabric and a matching ribbon page marker. Each volume will be bound with a "hubbed" spine that is characteristic of only the finest books. In every respect, this is to be a collection which rivals anything seen in the great private libraries of days gone by.

Exciting Diversity

The hallmark of a distinctive library is diversity. Therefore, the volumes in the

(continued on next page)

(continued from previous page)

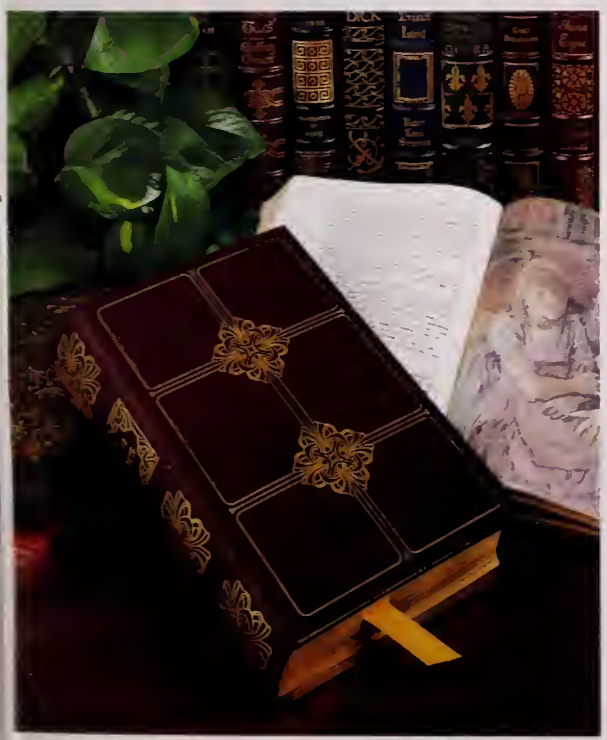
collection will vary in size, in the leathers used, in the distinctive cover designs, and in the illustrations. Yet the collection as a whole will exhibit an unmistakable harmony, because the volumes will be of consistent quality throughout.

Convenient Acquisition Plan

Because of the extreme care and craftsmanship required in printing and binding, the books in the collection will be issued at the rate of one per month. It will give you great pleasure to see your collection becoming more impressive with each passing month.

Comparable books bound in genuine leather command as much as $75 per volume. However, you will be pleased to learn that the volumes in this collection will be priced at only $33.50 each for the first two full years. Future volumes will be similarly priced subject to minor periodic adjustments to reflect varying material costs.

If you desire, you may return any volume within 30 days for a full refund. Moreover, you may cancel your subscription at any time.



R.S.V.P.

To accept this invitation, you need only complete the Preferred Subscription Reservation and return it to us. This simple step is all that is necessary for you to begin building a private library of your own that is sure to be envied by all who see it.

Last Chance to Buy at These Low Prices

This is the FINAL OFFER at these LOW PRICES. Inflationary pressures require a moderate price increase effective May 31, 1981. However, those who enter a new subscription before that date will be guaranteed price protection at current prices for the first two full years of enrollment. **Connecticut residents pay $37.90 to include sales tax.

Staff horticulturist at the Lamont-Doherty Geological Observatory of Columbia University, **Thomas A. Christopher** has a certificate in horticulture from the New York Botanical Garden and a degree in classics from Brown University. His article on the botanical garden at Padua grew out of his research on the history of the gardens of Italy, especially those of imperial Rome. Christopher points out that although "classics and horticulture may seem an unlikely combination of interests, the background in classics has provided me with the knowledge of languages and the techniques of research necessary for a study of historic gardens, while garden history has, in turn, provided a fascinating sidelight on the study of ancient and modern civilizations."

After the builders of the *Gossamer Condor* captured the Kremer Prize for human-powered flight in 1977, **Morton Grosser** was invited to join the team for its next project: the design and construction of the *Gossamer Albatross*, the plane that would make the first human-powered flight across the English Channel. Grosser's special responsibility, as an author and engineer, was to chronicle the *Gossamer* ventures in a book, a chapter of which has been adapted in this issue of *Natural History*. With a master's degree in mechanical engineering and a doctorate in the history of science, Grosser has been both a teacher and design engineer. He divides his time between writing and serving as an independent consultant in technology assessment and management.

When she arrived in Vermont in 1969 to teach folklore and folk life at Goddard College, **Eleanor A. Ott** (right) was fortunate enough to meet someone who could instruct her in the traditional ways of local rural life. This was Lucille Cerutti, who has shared with the author her lifelong experience of seasonal activities, from sap gathering and spring planting to deer hunt-

Mark Deyrup claims that he became interested in insects at the age of two, and that he made his first collection at the ripe age of four. An assistant professor of entomology at Purdue University, he is now engaged in investigating the biology of Indiana bark beetles and other insects that inhabit wood. The long-term goal of the project is to obtain information on the structure of insect communities in deadwood, the overlap of communities, and the niche breadth of in-

"I grew up with a great love of birds," writes **George W. Archibald**, "and kept an entire menagerie of ducks and geese at home in Nova Scotia. I remember doing my undergraduate thesis on cranes, being captivated by them, and going on to do graduate work on them." He has been working on the captive propagation of Siberian cranes since 1974, and is also doing research on the breeding ecology of red-crowned cranes and the migration and ecology of Siberian cranes in the USSR and the People's Republic of China, as well as the ethology of hooded cranes. Archibald is cofounder and a member of the board of directors of the International Crane Foundation in Baraboo, Wisconsin.

ing and the celebration of snowy winter holidays. The two have collaborated on making hog's head cheese, red flannel hash, and snapping turtle stew. In addition to Vermont folk life, history, and archeology, Ott's interests include Native American shamanism, stone monuments of prehistoric Britain, and the nesting habits and migration patterns of birds.

dividual organisms. Sequential change in communities and quantitative studies of insect-mediated decomposition rates will also be part of the research. In 1971 Deyrup began working on the Douglas fir beetles, but he soon began looking at the associates of the associated insects and became entangled in the community web. At present he is attempting to come up with a title for himself more euphonious and euphemistic than "deadwood entomologist."

Q. What is the WEBSTER'S NEW UNABRIDGED 20TH CENTURY DICTIONARY about?

A. It's about 2,300 pages and more than 4 inches thick!

For more than 40 years Webster's Unabridged Dictionary has served as an invaluable reference for students, teachers, businessmen, secretaries ... and workers in all trades and professions. The reason is simple. Here is a dictionary that supplies the need for accurate and full definitions, correct spellings and pronunciations, full etymologies, synonyms, as well as other general and specific information

A large staff of lexicographers and linguists has painstakingly edited and updated each definition so that it is clear, accurate, and readily understood in all its senses. Many new entries have been added, including recent additions to the language in the natural and social sciences, the humanities and other specialized branches of human knowledge

un à bridged', *a.* not shortened; complete; specifically, designating a dictionary that has not been abridged from a larger work.
un ac cent'ed, *a.* not accented; specifically, in

The large, clear, legible type shown above (actual size) "makes this unabridged dictionary the most readable one in print."

...now own one of the finest reference books in the world at only ⅓ of its originally published price.

The Country Music Foundation, Nashville, Tennessee,
is proud to announce its Official Archive Collection

THE GREATEST COUNTRY MUSIC RECORDINGS OF ALL TIME

**Unprecedented and unequaled in our time—
the complete and definitive collection of America's
country and western music.**

- *The best of 75,000 records from the Foundation archives and the vaults of every country music label.*
- *The first collection to include all the great country artists.*
- *Featuring all the great hits, the milestone performances, out-of-issue pressings and unreleased recordings.*

For the first time in history, the greatest recorded performances of country music's greatest artists will be brought together in a single, definitive collection. It will include the most important recordings by the leading country artists of today . . . landmark performances by legendary greats . . . and all the diverse and varied musical styles that have enriched America's country music.

This remarkable collection is the official issue of the Country Music Foundation – home of the Country Music Hall of Fame and Museum, and the world's largest library of recorded country music. And it is the first complete collection that the Foundation has ever issued honoring *The Greatest Country Music Recordings of All Time.*

A unique collection that only the Country Music Foundation could assemble

To assemble this collection, the staff of the Country Music Foundation carefully reviewed the Foundation's own archives of 75,000 records. In addition, they enlisted the support of all the country music record companies – whose vaults hold many of the master recordings selected for this collection. And they were able to obtain rare recordings from private collectors and country music artists themselves.

As a result, the Country Music Foundation Official Archive

"Country is the music of the people. Songs of the soil, forsaken and fulfilled love. Story songs whose music is both contemporary and timeless . . . I love it, and I am proud to be part of the first collection to tell the whole country music story."
—Johnny Cash

Collection is unique both in scope and importance. A collection that would be difficult – or impossible – for any individual to duplicate.

All the great performers

The collection will feature milestone recordings from the careers of country music's most important artists. Such *great contemporaries* as Loretta Lynn, with 'Blue Kentucky Girl,' 'Coal Miner's Daughter.' Kenny Rogers and The First Edition, with 'Ruby, Don't Take Your Love to Town.' Johnny Cash with 'I Walk The Line' and 'Sunday Morning Coming Down.' Dolly Parton, with 'Coat Of Many Colors' and 'My Tennessee Mountain Home.' The "outlaw" music of Willie Nelson. The Nashville sound of Chet Atkins and Eddy Arnold. Country rock, with The Charlie Daniels Band. And country classics by such other popular music artists as Linda Ronstadt, Glen Campbell and Anne Murray.

Also included will be the unforgettable recordings of such long-time *favorites* as Hank Snow, Ernest Tubb and Merle Travis. The *legendary giants:* Hank Williams, Patsy Cline, Jim Reeves, Flatt and Scruggs, and Jimmie Rodgers. And recordings that reflect regional influences and evolving musical styles – *bluegrass, Cajun, country gospel, western swing, honky tonk* and *rockabilly.*

The collection will include such *rare recordings* as Vernon Dalhart's 1924 recording of 'The Prisoner's Song' – country music's first million selling record, and Loretta Lynn's early classic 'Honky Tonk Girl' – now out of issue. And from the Foundation's archives will come *previously unreleased recordings* – studio "takes" never before made generally available.

Records of superior quality

Every step has been taken to ensure the *technical excellence* of the collection. Thus, all of the *early* recordings will first undergo a painstaking restoration process in the Country Music Foundation's newly opened Audio Restoration Laboratory. Here, recordings of classic performances will be electronically "cleaned" groove-by-groove to eliminate extraneous surface noise and preserve the original sound.

To produce the records, the Foundation has appointed The Franklin Mint Record Society – judged by audio experts to be a leader in producing records of superior quality. The vinyl used will be of a special formula containing its own anti-static element. This material, together with the careful process by which the pressing is made, results in a record that is more rigid, durable and resistant to dust. A true *proof-quality record* – providing exceptional tonal fidelity and clear, clean sound when played through any of today's audio systems.

In the Foundation's audio laboratory, the latest electronic techniques are used to restore the original sound quality of early recordings. Then, the records are pressed in a dust-free "clean room," where strict production standards, and audio and visual inspection, assure high quality.

Fascinating musical "program" in each album

Custom hardbound albums have been designed to house and protect all 100 proof-quality records in this collection.

Each album will contain two long-playing records, presenting a program of artists and recordings carefully selected by the Foundation, and unique to this collection. And each album will be accompanied by specially prepared program notes, illustrated with photographs from the Foundation's permanent collection.

Available by subscription only

If you have a long-standing interest in America's country music . . . or are just discovering its rich and exciting sound . . . this Official Archive Collection is an indispensable treasure. A complete, comprehensive and authoritative collection of the greatest recordings in country music – on records of exceptional fidelity.

The collection may be acquired only by direct subscription to The Franklin Mint Record Society, Franklin Center, Pennsylvania 19091. Subscriptions entered now will be accepted at the original issue price of just $9.75, plus $1.75 for shipping and handling, for each record. This price will be guaranteed for the entire series. Please note that the attached application is valid only if postmarked by March 31, 1981.

The Heirs of Disaster

The currents of change are obliging the people of a Mexican village to rethink their concept of the realm of the possible

By John L. Gwaltney

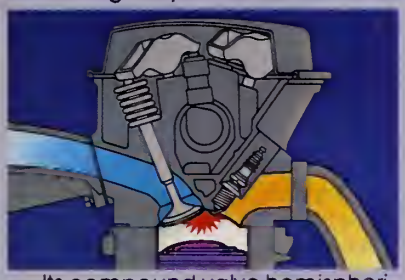
I remember the Mexican village of San Pedro Yolox when I left it in 1964 as preeminently civil, predominantly poor, and generally resigned to, but not content with, an astounding array of recurrent environmental trauma. "We are poor here so we drink our herb tea, burn our candles, make our vows, and hope for a miracle." The seventeen years that have intervened between the termination of my original fieldwork and a recent return visit to the Sierra Juárez have witnessed massive, multifarious change for San Pedro. As always the torrent of change has proved to be an intermittent stream. Many things remain what they were for all that innovation, but many others are profoundly, irrevocably altered.

Margaret Mead was one of the few practical, positive thinkers I have ever known. It was her lively mind and common sense that were instrumental in first placing me in the remote village of San Pedro Yolox, high in the eastern Sierra Madre. Eighteen years ago the proper intellectual disposition of a blind, black graduate student represented even more of a challenge to the imagination and humanity of senior scholars than it does now. The idea of sending a blind ethnologist to study the role and expectation of blindness in a village in the heart of the New World's onchocerciasis (river blindness) zone was Mead's response to that challenge.

So in 1963, while still acquiring "sierra legs," I trudged into San Pedro Yolox (at that time some three hours of hard walking from the nearest vehicular road), ready to begin a study of cultural accommodation to blindness and other environmental trauma in that Chinantec- and Spanish-speaking Sierra Juárez municipality.

Politically, San Pedro Yolox is a

The author, after an absence of seventeen years, returns to the village of San Pedro Yolox. Judith Gwaltney



FORD ESCORT. BUILT TO TAKE ON THE WORLD... AND DOING IT.

Outselling every import car line.

When this ad went to press, the American-built Ford Escort was outselling every import car line.†

And no wonder: Ford engineers worldwide teamed up to create this technologically advanced car.

Its compound valve hemispherical head engine gives you high mileage combined with power for freeway driving.

The manual transmission has a 4th gear overdrive standard. A new split-torque automatic is available.

The body design is as aerodynamic as some sports cars. Special steel, high-strength steel, reduces weight without sacrificing solidity.

Result: the compact Escort has better gas mileage ratings than subcompacts like VW Rabbit, Honda Accord, Toyota Corolla Hatchback—and, based on EPA Volume Index, more interior room, too.

44 EST HWY* **30** EPA EST MPG*

*Applies only to sedan without power steering or A/C. For comparison. Your mileage may differ depending on speed, distance, weather. Actual hwy mileage and Calif. ratings lower. Excludes diesels.

What about handling?

Front-wheel drive gives you traction for snow and wet roads. All-season steel-belted radials are standard.

Four-wheel independent suspension smooths the ride, grips the road. And for precise handling, there's rack-and-pinion steering.

Engineered to keep your driving costs down.

Escort has a chassis lubricated for life, 30,000 mile spark plugs, self-adjusting brakes and clutch, and the body is cathodically electrocoated to fight rust.

Most Escort models carry the lowest premium available from Allstate Insurance for any 1981 domestic car under their make and model rating program.

There's a lot more to know about Escort, and your Ford dealer is ready to help you do it. And, whether you buy or lease, don't forget to ask about Ford's Extended Service Plan.

THE NEW WORLD CAR.

†Based on comparison of manufacturers' U.S. retail deliveries of individual car lines.

Enter the world of Questers nature tours.

When you travel with Questers, you have the advantage of our knowledge of the travel world And our experience of the natural world We are travel professionals And our only tour program is Worldwide Nature Tours. You get reliable arrangements and expertly planned itineraries

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers rain forests, mountains, and tundra seashores, lakes, and swamps of the regions we visit. At the same time, we explore the more usual attractions in touring—the cities, archaeological sites, and people.

Where can you go with Questers? Virtually anywhere in the world The current Directory of Worldwide Nature Tours describes 32 tours varying from 9 to 30 days Following is a representative listing:

Worldwide Nature Tours
1981 Departures (Partial Listing)

The Americas

Everglades: 11 days, Mar. 26 & Nov 5 • Hawaii: 15 days, Feb. 15, Apr. 12, July 12, Oct. 11 & Dec. 20 • Alaska: 17 days, June 6 & 20, July 4, 11 & 25 & Aug. 8 • Newfoundland: 16 days, June 14 • Baja California: 11 days, Apr. 17 & Oct. 16 • Costa Rica & Panama: 16 days, Feb. 14, Nov 21 & Dec. 19 • The Amazon: 16 days, Jan. 19, May 11, July 6, Aug 10, Oct. 12 & Nov 16 • Peru: 23 days, Apr 4, July 18 & Nov. 7 • Ecuador & Galapagos: 15 days, Feb. 5 & 26, Apr 9, July 2, Aug 13 & Oct. 15 • Trinidad & Tobago: 11 days, Mar 9 & Nov 9.

Europe

Iceland: 16 days, June 12, July 3 & Aug. 7 • Islands & Highlands of Scotland: 23 days, May 29, July 10 & Aug. 21 • Spain: 18 days, Apr. 17 & Sept. 4

Asia and Africa

Indonesia: 24 days, July 14 & Sept. 8 • The Himalayas: 25 days, Mar. 19 & Oct. 8 • India: 21 days, Jan. 31 & Oct. 31 • Sri Lanka: 18 days, Feb. 19 & Nov. 19 • Kenya: 23 days, Feb. 5, July 23 & Oct. 22.

Oceania and Australasia

Australia & New Zealand: 30 days, Jan. 31 & Sept. 19 • New Zealand & the Milford Track: 22 days, Feb. 20 & Nov. 13

For a complimentary copy of the newest Directory of Worldwide Nature Tours outlining the entire program, write to Questers or see your Travel Agent. If you are interested in a specific tour, request the Detailed Itinerary. Exploratory expeditions and special tours are announced from time to time in our newsletter Nature Tour Notes, *sent free to all on our mailing list.*

QUESTERS

Questers Tours & Travel, Inc.
Dept. NH371, 257 Park Avenue South
New York, NY 10010 • (212) 673-3120

subdivision of the Oaxacan north escarpment district of Ixtlán. The centrally located village of San Pedro is the administrative center of the entire municipality of the same name. Culturally, Yolox is a distinct part of the western Chinantla, the traditional center of Chinantec cultures.

The Chinantla is a broken cross section of the Sierra Madre Oriental and the municipality of San Pedro Yolox displays the same ample microgeographical range that is characteristic of Mesoamerica in general. The village of Yolox, together with its environing hamlets (*ranchos* or *rancherías*), encompasses alpine, temperate, semitropical, and tropical zones. Elevations in the municipality range from 2,300 feet above sea level at its lowest extremity in Rancho Esperanza to more than 6,500 feet above sea level in the administrative center.

Once the arduous process of developing sierra legs is well enough advanced, it is possible to walk from the cold uplands above the central village, where the brisk air is filled with the scent of pines and cedars, to the tropical downcountry, where coffee, bananas, and lemon trees flourish. The elevated downslope portions of the municipality are by far the most productive. Coffee, which is the only cash crop, bananas, and vital building barks and vines are produced or gathered only in this region. However, the daughter streams of the Papaloapan River system that traverse this two-crop maize land are the breeding places of the several species of simuliids that are the intermediate hosts of the larva of *Onchocerca volvulus*. Larvae transmitted by the bite of these simuliids may mature and reproduce in human hosts. Successful *Onchocerca* colonies expand along such connective tissue as the optic nerve. Sustained infestation induces onchocerciasis, skin lesions, and an alteration in the color of the skin known locally as *mal morado* (the "purple sickness"). Transgenerational exposure to onchocerciasis has occasioned an abnormally high incidence of both economic and total blindness among Yoleños.

The Chinantec-speaking peoples are heir to a lengthy heritage of conquest. The expanding Aztecan state was industriously taxing and coercing them as the master mariners of Iberia were creeping westward. The conquistadors and the Dominicans forced them to gather hard by the marginal mountain wall, the better to watch and convert them. This legacy of subordination is manifest in the official name of the village. The Mexica (Aztecs) called it Yoloxochitlán, and the Spaniards called it San Pedro. It appears on maps as San Pedro Yolox, but its Chinantec inhabitants also call it Noo.

Onchocerciasis is perhaps the most spectacular of numerous disasters that make life hard for Yoleños. Months of fierce rain and hurricanes, the yawning earth and the serpent's mouth all take their mortal toll. This long history of subjugation and environmental trauma tends to make Yoleños publicly civil but privately wary before God and the powerful stranger.

In 1963 all cargo going into or leaving the village was carried on the backs of mules, horses, or men, but for all its remoteness, San Pedro was not isolated. The few radios of the municipality had conveyed the bad tidings of Mississippi and Alabama racism. I was assured by the municipal secretary in his welcoming address that I need have no fear of that particular kind of barbarism from Yoleños. Big-state Mexican ideas about health, education, and culture were being transmitted by visiting doctors, nurses, and teachers. A squad of federal soldiers was stationed there to prevent Yoleños or their neighbors from breaking the *pax Mexicana* by a rekindling of the traditional, bloody fighting for land. The Mexican government with its commitment to the modern notion of progress had launched a medical campaign against river blindness and other endemic diseases. In 1963 ideas such as progress and the germ theory of disease were among the abstractions that many Yoleños weighed respectfully in their scanty leisure. There were three kinds of economic status among the Yolox Chinantec. A very small group of families had shops and/or landholdings providing them with enough to eat of the foods that appeared in everybody's good dream diet. An overwhelming majority made wry jokes about their very real poverty, their fleas, and their frequent recourse to low-prestige foods. Turkey, chicken, and other prestigious animal protein were esteemed condiments for Yoleños, used most lavishly to add zest to fiesta dishes. A third group, a considerable number of families, were obliged by their extreme poverty to fast more often and resort even more frequently to the low-prestige foods

The Story of Civilization by Will and Ariel Durant

For more than a generation, Will and Ariel Durant have been tracing the continuity of our history—economic and political organization, science and art, religions, philosophies, customs and manners—to show the foundations of society today. Now complete, the Durants' 11-volume masterwork is history come alive. The enormous work covers ancient and modern civilization, including Oriental as well as Western history. With clarity and authority the Durants illuminate "the steps by which man passed from barbarism to civilization." This set is a magnificent centerpiece for any home library, and one of the most useful sources of knowledge that the modern reader can possess.

that figured largely in bad dream diets. This group was larger by far than the group with the most to eat.

In 1963 this pervasive poverty was reflected in the desultory attendance at the three-room elementary school of the village. The region of Yolox has excited the aesthetic admiration of many a foreign traveler, but those who must "pull bread from among these stumps and stones" long for the exalting of every valley and the lowering of every mountain and hill. When they say, "Our land is very ugly, nothing but mountains and trees," they mean that nine-tenths of it is impervious to even their arduous, complicated agricultural exertions. Those exertions and their prime end, to eat and, hence, to live, took precedence over education, the germ theory of disease, and the abstract imperatives of big-state Mexican culture.

Their complex agricultural regime scatters Yoleños over portions of every one of the microgeographical niches of their municipality. Only one Yoleño in seven belonged to a family that did not possess two dwellings, one in the *cabezera*, or municipal seat, and another, less substantial house of banana bark or some other tropical building material for use when the agricultural system mandated migration to the tropical *ranchos*. Fire-agriculture schedules varied in the almost vertical fields of their cold temperate and hot wet tropical zones. The loss of the labor of a child capable of agricultural work or the maintenance of a very young child in the centrally located village, site of the only school, represented a formidable strain upon the minimal resources of most Yoleños.

An abnormally large blind population was a serious burden upon the slender resources of many Yolox Chinantec. At least four out of ten Yoleños were related by ties of consanguinity or ritual kinship to a blind person. In 1963 at least 21 of the 963 Yoleños were blind, and most of these were obliged to ascend and descend their roller coaster trails driven by the same imperatives of hunger that goaded their sighted paisanos. Blindness was firmly established among the distressingly ample roster of traumatic customary expectations. Some villagers ate mescaline-bearing mushrooms or did the divinations that are done with various kinds of beans or maize grains to find out why life was unusually hard. But a hard,

chancy existence was quite reasonably considered normal, given their realities.

Divination or sorcery may explain or remedy misfortune occasioned by the malice of one's paisanos in this world or the next. Afflictions of God are not thought of as yielding to any form of human magic. Much of the Chinantec past has inclined them to roll with the political or supernatural punch. They are valiant in the defense of their sacred land and honored families, but it is a theological tenet with them that illimitable might is the sovereign aspect of God's nature. There was a pronounced tendency to think of the blind as His victims. Yoleños invariably dealt courteously and practically with blind people. Extravillage mendicancy was regarded as a necessity to which little stigma was attached. Blind Yoleño beggars accompanied by child guides ventured as far as Mexico City or Veracruz, although most begging expeditions were to neighboring villages. The easy, transgenerational deference that characterized the interaction of children as young as four or five with the middle-aged or elderly blind was a part of a general Yoleño tradition of practical civil identification with the handicapped. Most people defined a friend quite literally as "someone who feels your grief," and children walked with the blind "out of love." Without any significant exception, Chinantec of all generations extended the same civility to me. I was certainly the wealthiest and most technically encumbered blind person they had ever seen. One elderly woman saw an element of ill-defined menace in my metal canes, but most people were politely but openly curious about my Braillewriter and Braille watch. The sight of a blind person reading or typing was new to them, but most villagers were more interested than impressed by my devices. Their prime requirement is for a technology that minimizes drudgery and increases the yield of their grudging slopes.

The sense of awesome autonomy that often clings to technology in a machine culture was only nascent in Yolox in 1963. Humanity was still the measure of most things. I had to travel in their country in much the same way as any other blind person. My wealth made it possible for me to ride more often and hire the time and labor of people for my special purposes, but a child of eleven could see that my

SOUNDS THAT SOOTHE.

The Marsona sound conditioner generates the primal sounds of nature—the surf, the rain, the rhythmic gushes of a waterfall. And these sounds aren't recorded— but synthesized— with the use of advanced solid state electronics.

Hospitals use sound conditioners like the Marsona to relax patients in the coronary and respiratory care sections. Controlled laboratory tests at a university sleep lab indicated that sound conditioned sleepers got to sleep quicker, slept longer and received about 50% more Delta (stage 4) deep sleep.

Marsona's all-electronic design offers several advantages over earlier electro-mechanical models: more types of sounds (2 surf, rainfall, waterfall). There are no moving parts, no tapes, nothing to wear out. And it uses less electricity than a small night light.

And you can fine tune sounds to exactly your likes; from a mere whisper all the way up to a strong masking sound. With the surf you can even vary the rhythm from slow to fast to random.

The Marsona 1200 uses 'white noise'—long recognized by scientists for its ability to mask out unwanted noise that interferes with sleep, relaxation or work. We offer you the Marsona 1200 for a full two week money-back trial. One year warranty.

The changing seasons . . . and the delightful creatures of the forests. Portrayed in a collection of twelve charming collector's plates . . . one for each month of the woodland year.

Limited Signature Edition. Advance Subscription Deadline: March 31, 1981

The beauty and grace of a young deer frolicking in the summer meadow . . . the delight of a baby raccoon being startled by a tiny green frog . . . the charm of two chipmunks sharing their food with a little bird . . . such scenes from nature have a very special fascination for us all. To be able to capture these qualities in visual form is a unique gift – and the renowned English painter Peter Barrett has that rare gift in abundance.

Because Barrett is a trained naturalist as well as an artist, he is able to portray in his work not only the personality of nature's most captivating creatures – but also their distinctive features in realistic detail.

This distinguished wildlife artist will now undertake a uniquely challenging assignment. He will create a series of new works of art *exclusively* for a collection of twelve porcelain plates – plates that will depict woodland animals at play throughout the twelve months of the year.

Each of these works by Peter Barrett will be created for "The Woodland Year" porcelain plate collection, to be issued by Franklin Porcelain. And the first edition of this collection will be a special, limited "Signature Edition."

Each plate portrays a different animal . . . during a different month of the year

To capture the beauty of these woodland

The Friendly Chipmunks in August

scenes, Peter Barrett will depict each animal in a different natural setting . . . and during a different month of the year. And

Squirreling for Nuts in January

each delightful animal – the raccoon for April, the deer for June, the badger for October – symbolizes especially well that particular time of the year.

The January plate, for example, portrays two Grey Squirrels digging up acorns on a snowy winter's day. The May plate depicts a baby fox startled by the sudden appearance of a butterfly in the tall grass. The November plate shows an American Marten perched in a pine branch – a moment after he has mischievously disturbed a Red-Breasted Crossbill . . .

Every one of the twelve plates that make up the collection has a charm about it that is irresistible. Because no detail, no matter how small or subtle, escapes the eye of Peter Barrett.

A unique way to depict nature's most delightful creatures

Consummate artist that he is, Peter Barrett is always seeking ways to make his art different and original. And here he has found a most ingenious one. He has portrayed each scene as though it were being viewed secretly, without the animals knowing you were there. Thus, as you look at the plate, you have the illusion of having peered through an opening in the forest – and suddenly come upon this delightful scene! It's a technique which Barrett uses in the most winning manner . . . and each of the twelve works of art, therefore, becomes a new and pleasant surprise.

In order to capture the art of Peter Barrett in the most appealing manner, each plate will measure 9⅛ inches in diameter. Moreover, each of these lovely woodland plates will be decorated with a border of *pure 24 karat gold*. Franklin Porcelain has entrusted the creation of the plates for this distinguished collection to its affiliate, Franklin Porcelain of Japan.

Signature Edition available for a limited time

The Signature Edition of "The Woodland Year" by Peter Barrett will be distinctive because it is the *only* edition of this collection that will bear the signature of the artist on each plate.

In the tradition of fine porcelain, the plates in this desirable Signature Edition will be issued *only* during a single year – and will never be made available again. Thus, the total number of sets to be issued in the Signature Edition will be forever limited to the exact number of original subscriptions entered by the end of 1981, plus one set for the artist and one for the archives of Franklin Porcelain.

The collection of twelve plates will be sent to subscribers at the rate of one every *other* month, and the issue price for each plate is just $55, payable in two convenient

The Butterfly Chase in May

monthly installments of $27.50 each. This price is *guaranteed* to subscribers for each of the twelve plates in the collection, regardless of any rise in costs during the entire subscription period.

To enter your subscription for the Signature Edition of "The Woodland Year" – and begin to build one of the most beautiful collections in fine porcelain – mail your application to Franklin Porcelain, Franklin Center, Pa. 19091, by March 31, 1981.

new technology, except for the remote arcana of pursuits ethnological, was essentially sounding brass in his land. "You have a finger-writing machine and a finger watch and you give many little fiestas, but would it not be much better for you if your eyes were not clouded?"

The multilevel campaign of the Mexican government to integrate Chinantec and other indigenous ethnic communities into the national culture has intensified since 1964. The influence of what the Mexican media often call "that powerful gentleman, Don Petroleo," has probably caused a geometric acceleration of the scope and magnitude of this effort.

Seventeen years ago an elderly blind musician and pungent raconteur told me that "a dry trail would bring you anything." Now the widest of Yoleño trails has been converted into a dirt road that can carry the hardiest of motor vehicles into the administrative and commercial heart of the high village even in the time of summer rain, despite the several arroyos it must cross. Almost a half dozen of those who eat best own motorized vehicles.

The twenty-four men who take their seats and ceremonial staffs after All Saints' Day to govern the municipality meet in a new Municipal Palace. In this imposing, soon to be two-story administrative "House of Authority" there is very serious talk of driving a road through to the tropical downslope hamlets. At this writing, neither the internal combustion engine nor things electric are present in these *ranchos*. Their relative inaccessibility makes of these hamlets a kind of refuge area where the shadow of that insolence that often characterizes mountaineers still lingers. When the region's agricultural wealth is transportable by mechanical rather than animal or human exertion, when the tumpline and muleback have lost their dominion, the pace of innovation and integration will quicken definitively.

The three-room elementary school has been replaced by a thirteen-room educational plant with dormitory, latrines, and facilities for providing meals. Substantially freed from the often prohibitive costs of maintaining a very young child in the high village, many parents are willing, indeed anxious, to comply with compulsory education. For these children there will not be the same inferences of a necessary separation between education and culture because now Chinantec,

The start of a fine home library

Let us send you, for the token price of only $1 each, three books that have served as cornerstones in many a fine home library.

The complete works of Shakespeare

This beautiful 1300-page volume contains every word Shakespeare ever wrote. All 37 of his comedies, tragedies, and historical dramas including Hamlet, Romeo and Juliet, Macbeth, etc. Also all of his poems and sonnets.

The works of Kipling

Actually eight books in one. A complete novel and 139 stories, ballads and verses loved the world over, including Mandalay, Gunga Din, The Phantom Rickshaw, etc.

The works of De Maupassant

128 matchless tales by the acknowledged master of the short story. Every story complete and unexpurgated: The Diamond Necklace, A Piece of String, The Will, etc.

Each volume is clothed in a handsomely-tooled binding of antique ecru with both the elegant look and feel of leather.

You will enjoy reading these books, just as millions before you have. Your friends will admire them, perhaps even envy you for owning them. And your children will gain a real advantage with books like these always close at hand.

We offer you three books of this calibre for only $1 each to introduce you to our new Golden Giants Series. We think you will be impressed. And we hope you will want to own others in the Series, as they become available, including:

Hugo. 36 complete works including Hunchback of Notre Dame, A Woman of the Streets, The Souls.

Stevenson. 39 novels, stories, poems. Treasure Island, Dr. Jekyll and Mr. Hyde, Kidnaped, etc.

Doyle. All the best of Sherlock Holmes—The Sign of The Four, Red-Headed League, plus other works.

Poe. 91 works: Annabel Lee, The Raven, The Gold Bug, Murders in the Rue Morgue, etc.

The full series will also include the works of Cellini, Wilde, Ibsen, Browning, Longfellow, Emerson, Dostoevsky, Byron and many others.

Normally, you would expect to pay $12 each or more for deluxe editions of books like these. But our direct-to-the-public method of book distribution (which we have specialized in for over 50 years) lets us make these volumes available for only $7.89 each, plus shipping.

Send no money now. Simply mail coupon to get your first three volumes for only $1 each, plus shipping, and to reserve the privilege of examining future volumes as they come from the press.

You will receive advance description of all upcoming volumes. You may reject any book before or after you receive it. And you may cancel your reservation any time you wish.

Mail coupon to: Black's Readers Service, Roslyn, New York 11576.

Regularly $23.67. Now only $1 each.

Black's Readers Service

ROSLYN, NEW YORK 11576

Please enroll me as a subscriber and send me at once SHAKESPEARE, KIPLING and DE MAUPASSANT. I enclose *no money now*. After a week's examination, I will either keep my books and pay $3 (plus shipping) or return them.

Also reserve for me additional volumes in the Golden Giants of Literature Series. As a subscriber, I will get advance descriptions of future volumes. For each volume I choose, I will pay just $7.89 (plus shipping). I may return any book, for full credit within 21 days and I may cancel my reservation at any time.

Better Than Jogging

NordicTrack

Jarless Total Body Cardiovascular Exerciser Duplicates X-C Skiing for the Best Motion in Fitness

This revolutionary new exerciser duplicates the smooth, rhythmic, total body motion of X-C skiing for the most effective cardiovascular exercise obtainable. Uniformly exercises more muscles than any other exercise device. Makes high heart rates easy to obtain and keeps more muscles in tone. Also highly effective for weight reduction.

Completely jarless natural motion does not cause joint and back problems as in jogging or running. Arm and leg resistances are separately adjustable for maximum effectiveness. The NordicTrack uses no motors and folds compactly for convenience. Used in homes, businesses, and institutions. Our customers include Xerox Corporation, US Army, Penn State U and the YMCA.

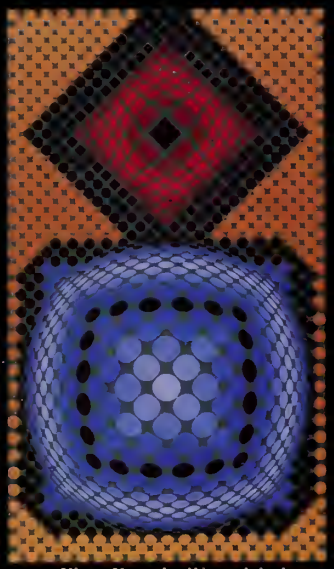
the rich, tonal, subtle, synonym-laden language of their homes, is spoken by fully half the staff of the new boarding school. Teachers are fluent in both Chinantec and Spanish, and this vital bilingualism is permitted and even encouraged in the classroom by the Instituto Nacional Indigenista, under the enlightened directorship of Dr. Salomón Nahmad. The Instituto is a Mexican national agency roughly equivalent to the United States Bureau of Indian Affairs.

The roster of customary calamities is being reduced. There are far fewer blind people in San Pedro now. The sardonic bandsman is no longer playing with the orchestras of this world. The lady who suspected that my steel canes might double as magical wands has gone on to the next world, as have about a dozen other elderly blind people.

There are no more assiduous soldiers in the ranks of progress than the brigades or paramedical teams of the Campaign Against Onchocerciasis. The effectiveness of their decades of therapeutic effort is plainly manifest in the drastically declining infection rate. Public education, the administration of antifilarial medications to everyone over the age of five, and the surgical excision of the nodules containing the adult filariae have eliminated blindness as a transgenerational expectation. The ranks of the blind are thinning because no new generation of severely infected men and women is emerging to fill them. Begging is not, even now, a thing of the past, but it is a much more precarious and much less satisfying activity than it was seventeen years ago. The resourceful, sighted, traditional junior partners of these adventurous secular pilgrimages are being sent to the new boarding school. Now those whose desire to relieve their penury or tedium is strong enough to impel them to take to the road must rely upon older, less trustworthy and less tractable guides who are often not fellow villagers. Begging is ultimately irreconcilable with the concept of progress, so increasingly, mendicancy is becoming that which Yoleño authority and public opinion will still permit but not approve.

The rich, strange mix of change is obliging the Yolox Chinantec to rethink their concept of the realm of the possible. "Life is easier and life is harder now." Most villagers have access to electricity but few use it, being too often away and occupied in the *ranchos*. Twenty-two public watertaps bring the mountain water closer to some of the high-village inhabitants and preclude the arduous necessity of hand carrying it all from the distant spring. The *jacal*, that most insubstantial of houses, has been relegated to the edges of the most remote of the high-village barrios and the dependent hamlets. Concrete and aluminum sheeting are increasingly preferred building materials, gradually forcing the traditional adobe out of use. Young men and women have learned new trades from the Cultural Mission of the Mexican government. The hand-hewn, often carved stools are rapidly being replaced by chairs fashioned by Yoleño carpenters, and the new, government-mandated latrines are being built by local masons. A number of seamstresses and human and veterinary paramedical specialists have been trained, but as yet these are not full-time occupations. A number of not altogether unsordid boons of progress have put in their appearance. Junk food is infinitely more available and that junkiest of junk foods, the airy stuff that often passes for bread in more progressive climes, is seriously competing with locally made wheat and corn breads, including even the ubiquitous tortilla. Television has made a very slight but palpable portentous hit in Yolox.



Rampant inflation has accompanied the increased reliance upon a money economy. The indispensable long machetes, yokes, axes, and palm fiber hats all cost ten times more than they did seventeen years ago. The price of staple and fiesta foods has increased even more. A new government store supplies such staples as beans, rice, maize, and cooking oil, and even some fiesta foods such as sardines, sugar, and cookies at lower prices than those prevailing in the privately owned shops. Since the government store does not extend credit, however, the poorest Yoleños are still locked into the credit regime at the three privately owned stores of the centrally located administrative village.

The earning power of Yoleños has increased at a much slower rate. There are augmented opportunities for those who own coffee trees or those who are willing to leave the municipality to work on distant coffee estates, but the voracious cost of living rapidly devours what they gain by five months of very hard labor.

What your home could have in common with the Met, the Tate, and the Louvre

Claude Weisbuch, *Concerto pour Violins et Lumière*, original lithograph. Edition of 250.

Victor Vasarely, *Mita*, original serigraph. Edition of 125.

Wilbur Streech, *River Moonlight*, original serigraph. Edition of 250.

Jarle Rosseland, *A Cold Day*, original woodcut. Edition of 225.

Nathalie Chabrier *Le Landau*, original lithograph. Edition of 250.

Louis Travert, *Roses Violettes*, original lithograph. Edition of 190.

In your own home, you can exhibit original work by artists who are represented in the world's great museums and galleries.

Artists like Calder. Chagall. Dali. Miró. Picasso. Vasarely.

At the Original Print Collectors Group, we offer moderately priced limited edition prints by these and other well-known artists.

Our offerings include signed original etchings, engravings, lithographs, woodcuts, and silkscreen prints.

Each print we offer is signed and numbered by the artist. Custom-framed. Accompanied by a certificate of authenticity and a full money-back guarantee.

And each print has been chosen not only for its beauty but for its investment value.

(Works by the artists we offer tend to appreciate, sometimes as much as 30% in a single year. Perhaps that's why *The Wall Street Journal*, *Business Week*, *Money*, AP, *Barron's* and UPI have quoted us as an authority on investing in art.)

For more information, send in the coupon. There's no obligation.

You'll find out about the special pleasure of owning original art, instead of just visiting it.

Judith Gwaltney

Seventeen years ago, beggars were aided by children who walked with the blind "out of love."

Some very basic strands of Chinantec life remain unaltered. Those who eat regularly and well still measure their maize crop by the ton. The large group of very small holders and the landless who secure rights to communal plots still measure the fruit of their exertion by mule loads.

About half the village householders have complied with the legal injunction to build proper latrines. But some are obliged to rent the use of these facilities now that "it is forbidden to sit down outside." The costly, thick rubber boots that people wear when working their hot humid downslope land will trap the fangs of vipers and all other venomous animals. But should these creatures elect to smite you upon the hand, you would still share the fate of the four ladies who died of snakebite in 1964.

The range of the massive wildcats that Yoleños call *tigres* has been restricted by the increased presence of humankind. They have retired farther into the mountains but "if you meet one there without a dog or a gun, you will remain there." The monkeys that live in the most remote parts of the central village and thrive in the tropical forest are safer now. The high cost of ammunition makes hunting game impractical for many.

The new municipal corn mill saves the women of the high village many hours of drudgery. But this new mill, the new road, and all the monumentality of progress have increased *tequio*, the tax of days of communal labor exacted from all able-bodied sons of the pueblo. A few are able to hire others to fulfill this obligation, but most must pay this increasingly burdensome tax out of their own muscle and at the expense of their own personal agricultural schedules.

Even if technology can effect a relenting of their hazardous environment, the quality of existence will not necessarily be improved. Social trauma, alcoholism, malicious and divisive gossip, and the fratricidal strife of factions over land must yield to reason and enlightened self-interest if life is to be really better. But seventeen years ago blindness was attributed to the will of God or even "the luck of each one," and now it is seen as a calamity that is yielding to human intervention. The hard lessons of a traumatic history and life in a merciless motherland have disinclined the wary, intelligent Chinantec to be the first by whom the new is tried. But if progress can make them victors over blindness, what prudent Yoleño can fail to weigh very seriously the prospect of even wider breaches in their wall of customary defensive conservatism.

Traditionally, the Chinantec were reluctant to "carry things to Mexico" and settled their affairs among themselves in juntas and in face-to-face interpersonal and communal consensus. Now they are cognizant of the inevitable encroachment of innovating bureaucracies and more than a little of the old fatalism remains, for not only does God "do as He pleases," but "paper talks." The degree to which the Chinantec will expand their view of the realm of the possible is in no small measure dependent upon the quality of their integration into general Mexican society, a process orchestrated by the powerful stranger.

John L. Gwaltney, professor of anthropology at Syracuse University, is author of Drylongso: A Self-Portrait of Black America *(Random House) and* The Thrice Shy: Cultural Accommodation to Blindness and Other Disasters in a Mexican Community *(Columbia University Press).*

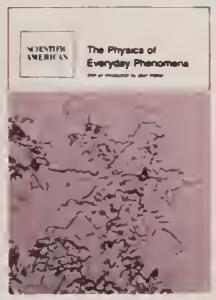
Toxic Tailings and Tolerant Grass

Adapted to mine soils contaminated with heavy metals, a species of grass in Wales provides an opportunity to learn about natural selection—and perhaps land reclamation

by Robert E. Cook

The tailings of abandoned mines hardly seem a fitting place to watch evolution. Vestiges of former excavations, they lie like forgotten scars on the face of the landscape. Rain rapidly drains through the coarse, porous soil, which holds little organic matter and few mineral nutrients. Toxic concentrations of heavy metals—zinc, copper, and lead—contaminate the sediments, rendering the ground water poisonous for most plants. Careful searching across this largely barren surface, however, frequently turns up tufts and large patches of grass that apparently tolerate the toxic metals and thrive under the stress of drought and mineral depletion. The successful adaptation of these rugged plants to derelict mines is a testament to the power of natural selection and provides a fine opportunity to study the process in operation.

More than one hundred years ago, Charles Darwin hinged his theory of evolution on the natural selection of individuals. Through the differential survival and reproduction of variants appearing in each generation, traits that adapt an organism to a particular habitat can increase in frequency in future generations. A century after the publication of *Origin of Species,* British geneticist Anthony Bradshaw and his students at University College of North Wales in Bangor set out to piece together a detailed picture of rapid adaptation among plants to the presence of heavy metals. To do so, they focused on the significance of natural variation.



Bradshaw and his students noticed that although pastures surrounding local mines were rich with species apparently unable to survive on the contaminated mine soils, there were some species growing in both habitats. For example, *Agrostis tenuis,* a wind-pollinated grass found in abundance in the pasture, forms sparse populations on mine soils. Two explanations of this phenomenon seem possible. On the one hand, perhaps certain species, such as *Agrostis,* possess a tolerance mechanism that enables them to extend their range to the excavation site. Alternatively, most of the pasture plants of *Agrostis* may not be able to tolerate heavy metals, and the colonizers of the mine may represent exceptional individuals that have adapted to the metals.

To determine which possibility is correct, researchers have developed an assay to measure the degree of tolerance possessed by an individual plant. They grow selected tillers or seedlings of a test plant in two solutions: one, the control, supplies only the nutrients found in normal soil; the second also contains a toxic concentration of a particular heavy metal. In the second nutrient solution, nontolerant plants do not grow roots, but the roots of tolerant individuals rapidly proliferate. Hence the vigor of the root growth in the toxic medium, compared with the growth in the control medium, provides a reliable index of tolerance. On this scale a rating of zero indicates a lack of tolerance, while a completely tolerant plant is rated ten.

Bradshaw sampled plants of *Agrostis* from a local mine and the surrounding pasture and grew them in the metal solution and the control. The tolerant plants rapidly rooted to form vigorous tillers, but the roots of the pasture plants were stunted and the shoots did not grow. The mine populations were clearly different from those found in the pasture and had evolved heavy metal tolerance since the original excavations. Moreover, although some mining operations date from the Middle Ages, many *Agrostis* populations have been discovered growing on mines less than one hundred years old; this evolution must be remarkably rapid.

Because the tolerant and nontolerant populations of *Agrostis* grow so close together, the explanation for such rapid evolution is more complex than simply quick adaptation to new conditions. Tolerant individuals of *Agrostis* grow well on mine soils in the presence of heavy metals and under harsh habitat conditions. Their offspring share their tolerance, indicating a strong genetic basis for this adaptation. In the pasture, nontolerant *Agrostis* survive nicely, competing

Is this the hand of the cuddly koala?

This powerful, clawed hand does indeed belong to the koala. It testifies to the rigorous adaptation of the animal to its tree-top habitat.

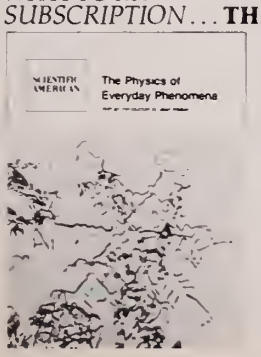
Commonly fancied as a lovable teddy bear, the koala is a marsupial, not a bear. The female koala, like her kangaroo cousins, has a pouch in which her offspring complete their embryonic development after they are born.

The koala's cuddly coat, which is not so cuddly close up, shelters it against all weathers. For dining, as the koala does exclusively on eucalyptus leaves, it is equipped with a digestive system that detoxifies the eucalyptus oil, a poison to any other animal.

The story of the shaping of the koala by natural selection in a recent issue of SCIENTIFIC AMERICAN, by Australian mammalogist Robert Degabriele, gave our readers new insight as well into a grander story—the process of evolution that shaped us all.

This is the kind of direct communication between the scientist and the interested layman that SCIENTIFIC AMERICAN conducts so admirably. In our magazine scientists in all disciplines report their new work and, in collaboration with our editors, place the work in its deepest perspective.

Why not join our more than 700,000 regular readers at the frontiers of knowledge? A diversity of interest awaits you in each monthly issue.



A one-year subscription is only $21. A two-year subscription at $38 saves $4. And a three-year subscription at $52 saves you $11.

Let Them Grow With a Questar
Children with intense curiosity about the nature of things will learn to master many tools, and the telescope, that prime tool of science, should be the first. Only the finest telescope, combining mechanical and optical perfection, can become a true extension of the mind and hand. Such an instrument is the Questar, and its lovely versatility adds an extra dimension to many fields: astronomy, terrestrial studies, or perhaps simply to the pure enjoyment of wildlife. What else could you buy a child that would enchant, amuse and continue to serve for a lifetime?
Send for our booklet in color on the portable, photovisual Questar. $2, please, to cover mailing on this continent. Airmail to S.A., $3.50; Europe and N. Africa, $4; elsewhere, $4.50.

vigorously with the wide array of other species in the field. The two populations meet at the boundary of the toxic soil. Since these plants are pollinated by wind, some pollen from each side fertilizes plants on the other side. As a result, some offspring on the mine side of the boundary should inherit nontolerant genes, and seed produced on the pasture side should display some tolerance.

This movement of genes in both directions could be expected to create an array of tolerances among offspring and a continuous transition zone from very tolerant plants well into the mine to very intolerant plants well into the pasture. Surprisingly, there is a very sharp break in the tolerance of the two populations, and the border between them is a clearly defined, sharp line. Although mine and pasture plants are only inches apart at the boundary, the mine individuals are fully tolerant, whereas the neighboring pasture plants fail to grow in the smallest concentrations of heavy metals. How is such a distinct boundary maintained in spite of the flow of genes back and forth between mine and pasture?

A critical tension exists between this movement of homogenizing genes between two different *Agrostis* populations and the selective factors working to maintain particular qualities of the populations. When wind-borne pollen carrying nontolerant genes crosses the border and fertilizes the gametes of tolerant females, the resultant offspring show a range of tolerances. The movement of genes from the pasture to the mine would, therefore, tend to dilute the tolerance level of seedlings. Only fully tolerant individuals survive to reproduce, however. This selective mortality, which eliminates variants, counteracts the dilution and molds a totally tolerant population. The pasture and mine populations evolve distinctive adaptations because selective factors are dominant over the homogenizing influence of foreign genes.

Thus evolution—the continuous sculpting of particular physiologies, morphologies, and behaviors—is accomplished through the differential survival of variants created in reproduction. Plants, because they do not move, lend themselves to observation of the process of evolution. The particular elegance of studying metal tolerance in *Agrostis* lies in our ability to measure variation and watch how it changes with each generation. Natural selection, which may ordinarily run long and slow, is captured in the act, held for inspection by the opposing flow of genes.

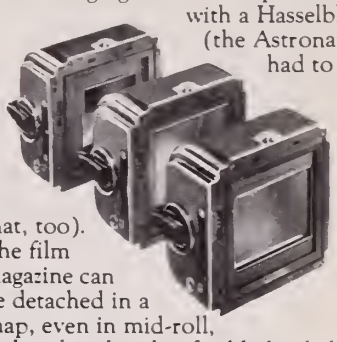
Tom McNeilly, a student of Bradshaw's, separated the effects of selection from the flow of genes by observing a population of *Agrostis tenuis* he found growing on a derelict copper mine in Caernarvonshire, Wales. The mine's surface, less than 985 feet across, sits on the floor of a U-shaped, glaciated valley whose steep slopes are covered with sheep pasture. McNeilly suspected that the east-west orientation of the valley, which strongly polarizes the prevailing winds in a westerly direction, might provide an appropriate setting for his work.

Toward the end of the summer, McNeilly collected seeds from a group of marked adult plants on the mine. He germinated thirty seeds and subjected the seedlings to the tolerance test in a nutrient solution with a toxic concentration of copper. The marked adults were then transplanted to a greenhouse where, isolated from the pasture plants, they formed a new batch of seeds exclusively through the exchange of pollen among themselves. These greenhouse seeds were also germinated and their seedlings tested for tolerance. Finally, the marked adults themselves were subjected to the copper solution. McNeilly could then compare the tolerance of adult plants with that of their greenhouse offspring; the tolerance of the same adult plants with that of their mine offspring; and, finally, the tolerance of the mine offspring with that of the greenhouse offspring.

The adult plants displayed a relatively narrow range of tolerance and had an average index between six and seven. A few individuals were as low as five, but considerably more displayed a high tolerance of seven. The seedlings that germinated from the isolated greenhouse seed also displayed an average tolerance between six and seven. As expected in offspring, however, the range of tolerance was greater: one of the seedlings was as low as three, while another, at ten, was completely tolerant. This wider variability among offspring compared with parents is the result of the recombination of genes, through sexual reproduction, into many different sets among the progeny. Because the average indexes of adults and their offspring were identical, we can conclude that the expression of tolerance is controlled by genes. Of more interest is

How good do you have to be to own a Hasselblad?

The reputation that Hasselblad enjoys as the choice of professional photographers and advanced amateurs might lead you to believe that it's a difficult camera to use. Nothing could be further from the truth. In many respects a Hasselblad is easier to use than other cameras, despite the extraordinary results it gives.



Consider the viewing system, for example. You don't have to squint with one eye through a tiny peephole. Instead your subject is projected big and bright onto the 2¼″ x 2¼″ ground glass screen. This makes it considerably easier to compose your photograph and to focus accurately. And what you see in the viewfinder is two-dimensional, just like your finished prints or slides.

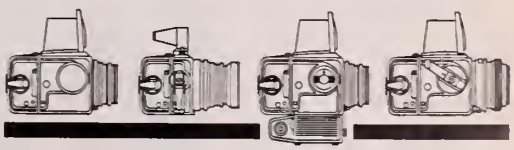
A further aid to creativity is the automatic depth of field indicator on the lens that gives you a choice of settings that will put the foreground or background in or out of focus.

A Hasselblad handles beautifully. It cradles comfortably in the palm of your hand. All controls are logically placed and easy to reach (the U.S. Astronauts were able to operate their Hasselblad cameras on the moon while wearing bulky gloves).

As a matter of fact, a Hasselblad lets you do things you can't do with a 35. Such as viewing and shooting with the camera held upside down overhead (great for shooting over crowds). Or for taking pictures at ground level without having to lie down (useful for nature photographs, or for shooting at unusual angles).

Changing film is a simple matter with a Hasselblad (the Astronauts had to do that, too).

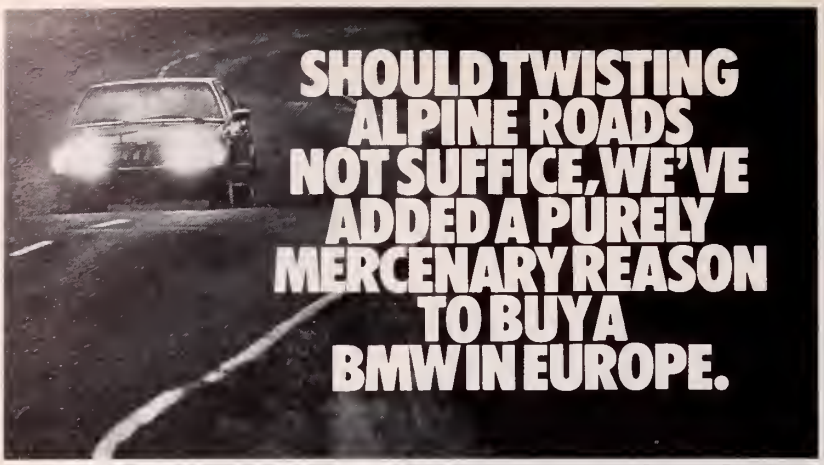
The film magazine can be detached in a snap, even in mid-roll, and replaced with a freshly loaded magazine or with a different type of film. This allows you to switch freely from black and white to color, from negative to positive film, or from daylight to tungsten. You can even switch formats. Your choices include the ideal 2¼″ square format; the 6 x 4.5 cm format, which enlarges to 8″ x 10″; or "superslides" that can be used with any 35mm projector, giving a dramatic, screen-filling image.



You also have access to a wide range of interchangeable lenses and accessories, because Hasselblad is the world's largest medium format system.

Creating a camera of such versatility and performance is no easy task. It takes a full year to build a Hasselblad. But then the lifespan of a Hasselblad is almost endless (ask any professional photographer). And Hasselblad's design philosophy of non-obsolescence assures that today's accessories will even fit a Hasselblad camera of twenty years ago.

So, how good do you have to be to own a Hasselblad? Just good enough to want a camera that can make you better.



See your Hasselblad franchised dealer, or write for one of our bulletins on square composition, and a comprehensive brochure on the Hasselblad system to:

Victor Hasselblad Inc.,

the broad range of tolerance among the progeny compared with the parents. For this new generation to display as adults the same *range* as their parents, the two extremes—low tolerance and high tolerance—would have to be eliminated. This elimination of extremes among offspring is, we believe, the measure of natural selection that maintains the tolerant adaptation among adults.

What about the tendency of gene flow from the pasture to dilute the effects of selection for tolerance? Here all is revealed by the mine offspring, germinated from seeds obtained from the adult plants still growing on the mine. The average tolerance of these seedlings is between four and five, well below that of the parents. The range of tolerance is broad, with three seedlings displaying the highest index of seven and one showing no tolerance at all. Remember, these are the individuals that under natural conditions would disperse across the mine to develop into the adults of the next generation. For the mine population to continue to have an average tolerance of six or seven, most plants with a tolerance below five would have to die. Three-quarters of this offspring population will indeed succumb to toxic concentrations of copper—a very strong selection.

The average tolerance of the mine seedlings is four or five, well below that of greenhouse seedlings at six or seven. This difference must be due to the migration of nontolerant genes: pasture pollen blows onto the mine, pollinates adults, and lowers the average tolerance of their progeny. Adult plants are capable of producing highly tolerant offspring when they interbreed in isolation, but when they grow on the mine in the presence of foreign pasture pollen, the highest tolerance of their offspring is seven. Thus, the population can never achieve total tolerance as long as mine individuals continue to cross with pasture plants. The force of natural selection is tempered by the flow of genes.

The polarity of the pollen-bearing wind in the valley where McNeilly worked permitted a field test of his findings. He marked off two transects across the boundary from the mine soils into the surrounding pasture: one was set across the prevailing wind, and the other ran downwind from the mine into the pasture. At selected locations McNeilly sampled plants and their seed, tested them for tolerance,

EXPLORE THE UNIVERSE FOR ONLY $2.95

Take this 4-volume Basic Astronomy Library for $2.95 (a $60.80 value

You simply agree to buy 3 more books—at handsome discounts—within the next 12 months.

Black holes, quasars, pulsars, supernovae, white dwarfs—explore the fantastic discoveries being made about the universe with this outstanding selection of four critically acclaimed astronomy books. Together they form a marvelously comprehensive Basic Astronomy Library.

Here is what your library will include:

WHITNEY'S STAR FINDER. *Charles A. Whitney.* Top-notch field guide to the heavens. Enables you to identify every major star in the sky over North America. Comes with a convenient Star Finder-Locater Wheel. Publisher's price $6.95

BLACK HOLES: The Edge of Space, The End of Time. *Walter Sullivan.* Bottomless pits into which whole stars can disappear . . . *Black Holes* takes you on an incredible journey that will change your picture of the universe. Hardbound. Publisher's price $17.95.

CATALOGUE OF THE UNIVERSE. *Paul Murdin et al.* Three-volumes-in-one: an atlas, encyclopedia and book of descriptive astronomy. Surveys over 220 astronomical objects. More than 300 photographs. Publisher's price $17.95.

THE ILLUSTRATED ENCYCLOPEDIA OF ASTRONOMY AND SPACE. Revised edition. *Edited by Ian Ridpath.* Your window to the universe. Over 1,000 entries and 150 photographs and illustrations. Hardbound. Publisher's price $17.95.

What is the Astronomy Book Club?

Astronomy Book Club is a very special club—one that is operated exclusively for astronomy enthusiasts. The Club is devoted to making the finest astronomy books available conveniently and inexpensively!

4 Good Reasons to Join

1. The Finest Books. Of the hundreds and hundreds of books submitted to us each year, only the very finest are selected and offered. Moreover, our books are always of equal quality to publishers' editions, *never* economy editions.

2. Big Savings. In addition to getting the BASIC ASTRONOMY LIBRARY for only $2.95 when you join, you keep saving substantially—up to 30% and occasionally even more. (For example, your total savings as a trial member—including this introductory offer—can easily be over 50%. That's like getting every other book free!)

3. Bonus Books. Also, you will immediately become eligible to participate in our Bonus Book Plan, with savings of at least 70% off the publisher's price on any book offered in the Club.

4. Convenient Service. At 3-4 week intervals (16 times per year) you will receive the Book Club News, describing the Main Selection and Alternate Selections, together with a dated reply card. If you want the Main Selection, do nothing and it will be sent to you automatically. If you prefer another selection, or no book at all, simply indicate your choice on the card, and return it by the date specified. You will have at least 10 days to decide. If, because of late mail delivery of the News, you should receive a book you do not want, we guarantee return postage.

Astronomy Book Club L-AH8
Riverside, New Jersey 08075

Please accept my application for trial membership and send me the BASIC ASTRONOMY LIBRARY—G(10160) for $2.95. I agree to purchase at least three additional Selections or Alternates over the next 12 months. Savings range up to 30% and occasionally even more. My membership is cancelable any time after I buy these three books. A shipping and handling charge is added to all shipments.

No-Risk Guarantee: If you are not satisfied—for any reason—you may return your introductory books within 10 days and your membership will be canceled and you will owe nothing.

and compared the average index of parent and offspring to distinguish the effects of gene flow.

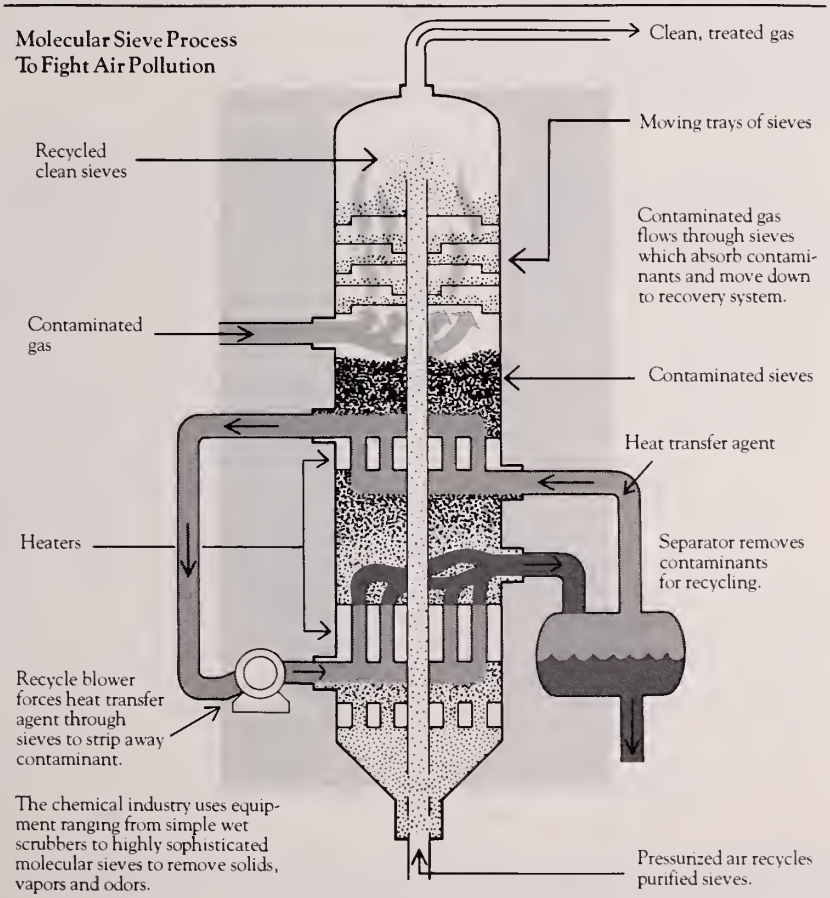
As expected, adult plants on the mine side of the first transect, running crosswind, are quite tolerant, with an index of six. The seedlings they produce have a considerably lower tolerance of about four. The difference in the tolerances of the adults and their seedlings provides a measure of the movement of nontolerant genes onto the mine soils. As McNeilly sampled closer and closer to the boundary between the mine and the pasture, the tolerance of both adults and offspring gradually dropped, to about four and three, respectively. About sixty-five feet into the pasture, *Agrostis* seedlings had a tolerance index of just over one—identical to that of the parent plants and close to that of completely nontolerant *Agrostis*.

The second transect presented a very different picture. Close to the boundary on the mine side, tolerance among adults was high, at five. The tolerance of the seedlings of these plants was only a single index point lower, possibly indicating the slight effects of pasture pollen from the upwind side of the mine. Surprisingly, this situation remained the same for more than 165 feet downwind into the pasture. Adult plants of *Agrostis tenuis* growing on pasture soil displayed a high index of tolerance and so did their progeny. Clearly there was a great infiltration of tolerant genes into the pasture population. At 230 feet from the boundary, however, the entire situation was reversed. There parent plants had a tolerance index of three while that of their seedlings was much higher, between four and five. At the last station sampled, almost 500 feet from the mine, progeny still displayed a relatively high tolerance, between three and four, although their parents, with an index of two, were nearly nontolerant. This phenomenon can only be explained by two processes: the constant migration of tolerant genes from the mine, which continues to produce higher tolerance in seedlings each generation, combined with strong selection *against* metal-tolerant seedlings in nontolerant pasture populations. Tolerant genes, which adapt plants to growth in soils with high copper content, are acquired at a cost: such individuals cannot survive in normal pasture populations.

We do not fully understand the biology behind this constraint. It may

Clearing the Nation's Air

What the chemical industry is doing to help clean up the air you breathe



Today, almost all of our industry's plants meet or exceed Environmental Protection Agency clean air requirements. But we're not stopping there. Here are some of the ways we're helping America breathe easier:

1. Committing billions to clean up

The chemical industry is investing more than any other U.S. manufacturing industry in fighting pollution, according to the U.S. Census Bureau. Since 1976, we've doubled our investment in air pollution control equipment. By the end of 1979, this commitment exceeded $2.6 billion. We are also investing millions of dollars in environmental research. The expenditures for one research program alone are expected to exceed $9 million by the end of 1980.

2. Upgrading plants and processes

New plant construction includes sophisticated equipment and technology. Older, existing plants are being refitted with additional equipment to improve emission control and meet environmental requirements. We're also finding ways to recycle emissions to create useful raw materials.

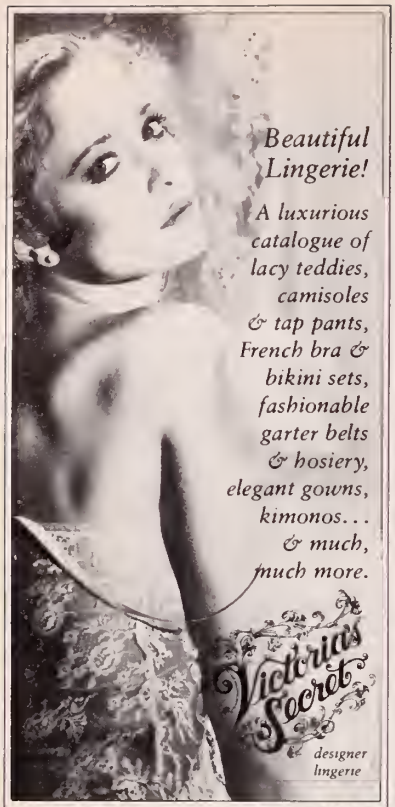
The chemical industry uses equipment ranging from simple wet scrubbers to highly sophisticated molecular sieves to remove solids, vapors and odors.

3. Trapping particulates more effectively

A scrubber at one company helps trap more than 1,300 tons of particulate sulfur each year. Electrostatic precipitators help reduce fly ash emissions by nearly 100 percent. "Baghouses," which operate like household vacuum cleaners, also help keep dusts and solid particles from contaminating the air.

4. Capturing vapors with new technology

Research is helping us find new and better ways to control gaseous wastes. For example: a highly specialized molecular sieve recovers waste sulfur dioxide from the vent gas of sulfuric acid plants for recycling into the acid-making process. Special incinerators help control odorous gases. We've created compounds which can trap specific kinds of pollutant molecules.



5. Getting more employees involved

We have more than 10,000 employees whose sole job is to operate, maintain and monitor pollution control equipment. And we add to this number each year. At one facility, employee programs encouraged ideas which helped eliminate 75,000 tons of air pollutants each year.

For a booklet that tells more about what we're doing to protect the environment, write: Chemical Manufacturers Association, Dept. GL-103, P.O. Box 363, Beltsville, Md. 20705.

involve the tolerance mechanism, which seems to enable the plant to sequester the toxic metals in an innocuous complex in the cell walls. We do know that without neighbors, tolerant plants are perfectly capable of growth on pasture soils. Competition with normal plants completely suppresses them in pastures, however, and garden experiments with mixtures of the two inevitably lead to the dominance of the pasture plants. The tolerant individuals seem unable to corner their share of light, nutrients, and water. Plants found on mines generally differ from nontolerant specimens in many ways, however, so this competitive inferiority may derive from biological characters other than the tolerance mechanism. One study of zinc-tolerant *Anthoxanthum odoratum,* sweet vernal grass, found that such individuals are smaller in stature than nontolerant plants, have smaller leaves, and are able to grow more effectively in soils with low levels of nutrients. They also flower earlier in the season and self-pollinate at a high frequency. Such reproductive characteristics tend to isolate the mine population from the flow of foreign pollen, which would otherwise lower the average tolerance among progeny. This incipient reproductive isolation of an interbreeding group of plants is the first step on the path to speciation. Perhaps the evolution of what are now two populations of *Agrostis tenuis* will in time result in the formation of two independent species.

The metal tolerance story has a pleasing epilogue in the real world of land reclamation. Bradshaw has turned his attention to the use of tolerant populations in the revegetation of contaminated soils. Derelict mines are more than an eyesore; they are also subject to severe gully and sheet erosion from surface drainage and wind. The flooding of neighboring streams and the contamination of ground water redistributes toxic spoils into surrounding pasture and agricultural land, sterilizing the vegetation and endangering grazing livestock.

In 1969 Bradshaw and his students began experiments at a number of sites. Preliminary testing of the soils revealed that phosphorus is a major nutrient limiting the establishment of plants over the whole surface. At each site they laid out a set of small half-yard plots differing in topography and applied a series of fertilizer treatments to facilitate initial growth of seedlings. They harvested seeds of tolerant populations of *Agrostis tenuis* and several other tolerant species from contaminated mines and sowed them at high densities, along with commercial, nontolerant seeds that served as controls. When growth was assessed at the end of a year, tolerant plants consistently outyielded nontolerant plants. Fertilizer applications were essential, however, and the pH of the soil determined which tolerant species were most successful: *A. tenuis,* for example, prefers strongly acidic conditions.

These experimental populations of tolerant plants proved remarkably persistent, maintaining vigorous growth for more than nine years. The conventional process of reclamation involves the surface addition of a layer of sewage sludge or topsoil, followed by the sowing of commercial varieties of grass. Bradshaw has calculated that the cost of using metal-tolerant populations with appropriate fertilizer treatments may be less than one-sixth the cost of the traditional method.

Like the best of biomedical science, Bradshaw's study of heavy metal tolerance is a paradigm of rigorous research and a prescription for increasing our well-being. But by focusing on the meaning of variation, evolutionary biology differs from medical biochemistry and physiology, where variation is often considered an unfortunate experimental error. Biomedical investigators tend to concentrate on the commonness of events, on the average pattern seen beneath the glass. Students of ecology and evolution, by contrast, are concerned with the rich pageant of diversity in nature. Far from an annoyance to be minimized by meticulous control, natural variation is recognized as essential to answering the question, Why are there so many kinds of living things?

The answer can have practical applications. Today, the National Seed Development Organization, for example, is selling cultivars of metal-tolerant *Agrostis tenuis* ready for use in reclamation. In a day when each dollar of the U.S. government's budget for pure science is subjected to intense scrutiny and each week reveals a new chemical dump in someone's backyard, we may look to Bradshaw's work for inspiration. Creative, rigorous science need not always be expensive, inexplicably abstract, or irrelevant.

Robert E. Cook is associate professor of biology at Harvard University.

Kingdoms Without Wheels

Why can't living creatures—at least most of them—evolve wheellike feet?

by Stephen Jay Gould

Sisera's mother thought fondly of the booty that her son might bring back—"a prey of divers colors of needlework"—after meeting the armies of Israel led by Deborah and Barak (Judges, chapters 4–5). Yet he was overdue, and she began to worry: "Why tarry the wheels of his chariots," she inquired anxiously. And rightly did she fear, for Sisera would never return. The Canaanite armies had been routed, while Jael had just transfixed Sisera through the head with a nail (a tent post in modern translations)—ranking her second to Judith among Jewish heroines for the gory dispatch of enemies.

Generals of the biblical armies rode on chariots; their apparatus traveled on carts. But two thousand years later, by the sixth century A.D., the question posed by Sisera's mother could no longer be asked, for wheels virtually disappeared as a means of transportation from Morocco to Afghanistan. They were replaced by camels (Richard W. Bulliet, *The Camel and the Wheel*, Harvard University Press, 1975).

Bulliet cites several reasons for this counterintuitive switch. The Roman roads had begun to deteriorate and camels were not bound to them. Craftsmanship in harnesses and wagons had suffered a sharp decline. But, most important, camels (as pack animals) were apparently more efficient than carts pulled by draft animals (even by camels). In a long list of reasons for favoring camels to nonmechanized transport by wheels, Bulliet includes their longevity, endurance, power of abstinence from food and water, ability to ford rivers and traverse rough ground, and savings in manpower (a wagon requires a man for every two animals, but three to six pack camels can be tended by a single person).

We are initially surprised by Bulliet's tale because wheels have come to symbolize in our culture the sine qua non of intelligent exploitation and technological progress. Once invented, their superiority cannot be gainsaid or superseded. Indeed, our standard metaphor for deriding the repetition of such obvious truths proclaims that such a dull speaker must be trying to "reinvent the wheel." In an earlier era of triumphant social Darwinism, wheels stood as an ineluctable stage of human progress. The "inferior" cultures of Africa slid to defeat; their conquerors rolled to victory. The "advanced" cultures of Mexico and Peru might have repulsed Cortés and Pizarro if only a clever artisan had thought of turning a calendar stone into a cartwheel. The notion that carts could ever be replaced by pack animals strikes us as not only backward but almost sacrilegious.

The success of camels reemphasizes a fundamental theme of these columns: adaptation, be it biological or cultural, represents a better fit to specific, local environments, not an inevitable stage in a ladder of progress. Wheels were a formidable invention, and their uses are manifold (potters and millers did not abandon them, even when cartwrights were eclipsed). But camels may work better in some circumstances. Wheels, like wings, fins, and brains, are exquisite devices for certain purposes, not signs of intrinsic superiority.

The haughty camel may provide enough embarrassment for any modern Ezekiel, yet this column might seem to represent still another blot on the wheel's reputation (though it does not). For I wish to pose another question that seems to limit the wheel. So much of human technology arose by re-creating the good designs of organisms. If art mirrors nature and if wheels are so successful an invention, why do animals walk, fly, swim, leap, slither, and creep, but never roll (at least not on wheels)? It is bad enough that wheels, as human artifacts, are not always superior to nature's handiwork. Why has nature, so multifarious in her ways, shunned the wheel as well? Are wheels a poor or rarely efficient way to make progress after all?

In this case, however, the limit lies with animals, not with the efficiency of wheels. A vulgarization of evolution, presented in many popular accounts, casts natural selection as a perfecting principle, so accurate in its operation, so unconstrained in its action, that animals come to embody a set of engineering blueprints for optimal form. Instead of replacing the older "argument from design"—the notion that God's existence can be proved by the harmonies of nature and the clever construction of organisms—natural selection slips into God's old role as perfecting principle.

But the proof that evolution, and not the fiat of a rational agent, has built organisms lies in the imperfections that record a *history* of descent and refute creation from nothing. Ani-

The world is still wondering how o people who had not yet conceived of the wheel, manoged to plon ond build Mochu Picchu, a city so odvonced in orchitecture ond rood system.

It is not within the power of words to convey the visual excitement of Peru This is o country so voried thot it makes you wonder how mon ever leorned to dominote it. With the oceon, the Andes ond the Amozon competing for ottention, the eye is forever engoged No other combinotion of elements could exert such on hypnotic effect on the visitor.

In dromotic controst with its incomporoble ontiquities is Peru's modern copitol, stunning Limo However troveled, the tourist will not have found more impressive hotels on either side of the oceon, nor enjoyed more interesting food so grociously served

It is often soid thot Limo is like o huge museum, with such religious ond historicol relics os the Cothedrol on the Plozo de Armos where the remoins of the conquistodor, Pizarro, ore displayed in o gloss coffin. Neorby is the church of Son Froncisco, with catocombs rivoling those of Rome ond priceless ort treosures by well known mosters.

UNSPOILED.

There are few places left on earth that are unspoiled. Sri Lanka is one of them. Once known as Ceylon, Sri Lanka has Asia's best game preserves. 200 species of animals, 425 kinds of birds and hundreds of square miles of leopard, elephant and sambur.

The wild flowers of Sri Lanka include a dazzling display of orchids. And where else could you find 600,000 acres of tea gardens on misty mountains?

There are 75 ways you can tour Sri Lanka. Ranging from 3 to 21 days. Accommodations begin at $5. Deluxe sells for $45. Never has your dollar worked harder. From shopping to sightseeing.

In our ancient cities, you can enjoy frenetic festivals that reflect the unspoiled nature of a culture which dates back 3,000 years.

Whether your visit is pleasure, business or a convention, our unspoiled country will spoil you. Just one hour from India, three hours from Katmandu, Bangkok and Singapore. Write for a color flyer and tour digest that includes special airfare.

RESEARCH MONIES AVAILABLE

The Winchester Museum, Buffalo Bill Historical Center, announces the availability of research monies through its Kinnucan Arms Chair Endowment Fund. The Kinnucan Arms Chair supports original research and development of scholarly studies relating to firearms in the areas of history, evolution, technology and aesthetics. Projects need not be restricted to Winchester-related subjects, but it is required that the Winchester arms collection be utilized as a source of information and research.

Inquiries for further information should be addressed to the Kinnucan Arms Chair, Buffalo Bill Historical Center, P.O. Box 1000, Cody, Wyoming, 82414.

mals cannot evolve many advantageous forms because inherited architectural patterns preclude them. Wheels are not flawed as modes of transport; I am sure that many animals would do far better with them. (The one creature clever enough to build them, after all, has gotten some mileage from the invention, the superiority of camels in certain circumstances notwithstanding.) But animals cannot construct wheels from the parts that nature provides.

As its basic structural principle, a true wheel must spin freely without physical fusion to the object it drives. If wheel and object are physically linked, then the wheel cannot turn freely for very long and must rotate back, lest connecting elements be ruptured by the accumulated stress. But animals must maintain physical connections between their parts. If the ends of our legs were axles and our feet were wheels, how could blood, nutrients, and nerve impulses cross the gap to nurture and direct the moving parts of our natural roller skates? The bones of our arms may be unconnected, but we need the surrounding envelopes of muscle, blood vessels, and skin—and therefore cannot rotate our arms even once around our shoulders.

We study animals to illuminate or exemplify nature's laws. The highest principle of all may be nature's equivalent of the axiom that for every hard-won and comforting regularity, we can find an exception. Sure enough—somebody out there has a wheel. In fact, at this very moment, wheels are rotating by the millions in your own gut.

Escherichia coli, the common bacillus of the human gut, is about two micrometers long (a micrometer is one-thousandth of a millimeter). Propelled by long whiplike threads called flagella (singular, flagellum), an *E. coli* can swim about ten times its own length in a second. Lest swimming seem easy for a creature virtually unaffected by gravitational forces and moving through a supporting and easily yielding fluid, I caution against extrapolating our view to a bacterium's world. The perceived viscosity of a fluid depends upon an organism's dimensions. Decrease a creature's size and water quickly turns to molasses. Howard C. Berg, the Colorado biologist who demonstrated how flagella operate, compares a bacterium moving in water to a man trying to swim through asphalt. A bac-

ANNOUNCING A MOST IMPORTANT NEW PORCELAIN PLATE COLLECTION . . .

THE GREAT CATS

BY PETER SKIRKA

AN EXCEPTIONAL SERIES OF EIGHT COLLECTOR'S PLATES BY OUTSTANDING WILDLIFE ARTIST PETER SKIRKA . . . HIS FIRST WORKS OF ART ON PORCELAIN.

EACH OF THE EIGHT PLATES BEARS A NEW AND ORIGINAL WORK CREATED BY MR. SKIRKA EXCLUSIVELY FOR THIS LIMITED EDITION.

EDITION LIMITED ONLY TO 5,000 SETS.

AVAILABLE BY SUBSCRIPTION ONLY.

"TIGER"

ILLUSTRATIONS SHOWN SMALLER THAN ACTUAL SIZE (9¼" DIAMETER)

The great cats. Some of the most magnificent animals in existence. An existence that becomes more endangered with each passing year.

But now, through the artistic brilliance of Peter Skirka, you can preserve forever in your home the beauty of eight of these stunning animals. For Peter Skirka, one of America's most outstanding and highly honored wildlife artists, has created his first works of art to be reproduced on fine porcelain—*The Great Cats*—a series of eight collector's plates portraying the beauty, strength, and mystery of eight of nature's most superb creatures. And as the *first* works on porcelain by this most exceptional artist, this collection is destined to have lasting importance.

Included in the collection will be the *Tiger, Leopard, Lion, Jaguar, Puma, Cheetah, Black Panther,* and *Snow Leopard.*

Commissioned by the American Collector's Guild, Ltd., the plates—a full 9¼" in diameter and with a border of precious 23 karat gold—will bear the hallmark of Phoenix Fine China, one of America's premier names in fine-art porcelain china. The exceptional whiteness and translucence of fine porcelain china are ideally suited to bring out the subtle colors and precise details of Peter Skirka's art.

The Great Cats porcelain plate collection will be strictly limited to an edition of only 5,000 sets, and will be available by subscription only. Further, to protect the integrity of the edition, no subscriber will be permitted to order more than two sets.

The collection will be issued to subscribers at the convenient rate of one plate every six weeks. The issue price of only $55 per plate will include specially written reference material, Certificate of Authenticity, and special display stand for each plate. Due to the time and care required for the crafting of each plate in this superb collection, please allow 6 to 8 weeks for delivery of *Tiger*, your first plate.

Note: If you provide your credit card number, we will automatically charge each plate shortly before it is shipped, unless you instruct us otherwise.

RESERVED SUBSCRIPTION

AMERICAN COLLECTOR'S GUILD LTD., 251 ESSEX STREET, MILLBURN, NEW JERSEY 07041

Please enter my subscription for **The Great Cats** porcelain collection, consisting of eight 9¼" plates bearing original works of art by Peter Skirka, to be sent to me at the rate of one plate every 6 weeks at the original issue price of $55* per plate. I enclose payment in full of $55* for the first plate—Tiger—and agree to pay for each succeeding plate as invoiced prior to its shipment. (*New Jersey residents add 5% sales tax.)

JACK DANIEL TANSY JULEP CUP

Here's a most elegant way to enjoy Mr. Jack's favorite drink. He used to pluck some fresh tansy from his garden, crush a few lumps of sugar, and sweeten it with a dollop or two of his famous whiskey. You can too with this elegant polished pewter cup made exclusively for our friends. It has the famous Jack Daniel signature engraved on the side and holds a manly 12 ounces, (4½" tall). My **$24.50** price includes delivery.

Send check, money order or use American Express, Visa or Master Charge, including all numbers and signature

(Tennessee residents add 6% sales tax.)

For a catalog full of old Tennessee items and Jack Daniel's memorabilia, send $1.00 to the above address. Telephone 615-759-7184

terium cannot coast. If its flagella stop moving, a bacterium comes to an abrupt halt within about a millionth of its body length. The flagella work wonderfully well in trying circumstances.

After Berg had modified his microscope to track individual bacteria, he noted that an *E. coli* moves in two ways. It may "run," swimming steadily for a time in a straight or slightly curved path. Then it stops abruptly and jiggles about—a "twiddle" in Berg's terminology. After twiddling, it runs off again in another direction. Twiddles last a tenth of a second and occur on an average of once a second. The timing of twiddles and the directions of new runs seem to be random unless a chemical attractant exists at high concentration in one part of the medium. A bacterium will then move up-gradient toward the attractant by decreasing the probability of twiddling when a random run carries it in the right direction. When a random run moves in the wrong direction, twiddling frequency remains at its normal, higher level. The bacteria therefore drift toward an attractant by increasing the lengths of runs in favored directions.

The bacterial flagellum is built in three parts: a long helical filament, a short segment (called a hook) connecting the filament to the flagellar base, and a basal structure embedded in the cell wall. Biologists have argued about how bacteria move since Leeuwenhoek first saw them in 1676. Most models assumed that flagella are fixed rigidly to the cell wall and that they propel bacteria by waving to and fro. When such models had little success in explaining the rapid transition between runs and twiddles, some biologists suggested that flagella might tag passively along and that some other (and unknown) mechanism might move bacteria.

Berg's observations revealed something surprising, hinted at and proposed in theory before, but never adequately demonstrated: the bacterial flagellum operates as a wheel. It rotates rigidly like a propeller, driven by a rotatory "motor" in the basal portion embedded in the cell wall. Moreover, the motor is reversible. *E. coli* runs by rotating the flagella in one direction; it twiddles by abruptly stopping and rotating the flagella the other way!

Berg could observe the rotation and correlate its direction with runs and twiddles by following free-swimming bacteria in his machine, but S.H. Larsen and others, working in Julius Adler's laboratory at the University of Wisconsin, provided an even more striking demonstration. They isolated two mutant strains of *E. coli*—one that runs and never twiddles and another that twiddles incessantly. They "tethered" these mutant bacteria to glass slides, using antibodies that attach either to the hook or filament of the flagella and also, fortunately, to glass. Thus, the bacteria are affixed to the slide by their flagella. Larsen noted that the tethered bacteria rotate continually about their immobilized flagella. The running mutants turn counterclockwise (as viewed from outside the cell), while the twiddling mutants turn clockwise. The flagellar wheel has a reversible motor.

The biochemical basis of rotation has not yet been elucidated, but the morphology can be resolved. Berg proposes that the bottom end of the flagellum expands out to form a thin ring rotating freely in the cytoplasmic membrane of the cell wall. Just above it, another ring surrounds the flagellar base, but is not attached to it. This second ring is mounted rigidly on the cell wall. The lower ring (and entire flagellum) rotates freely, held in position by the surrounding upper ring and the cell wall itself.

Some exceptions in nature are dispiriting—the nasty, ugly, little facts that spoil great theories in Huxley's aphorism. Others are enlightening and serve only to reinforce a regularity by identifying both its scope and its reasons. These are the exceptions that prove (or probe) rules—and the flagellar wheel falls into this happy class.

Is it accidental that wheels only occur in nature's smallest creatures? Organic wheels require that two parts

be juxtaposed without physical connection. I argued previously that this cannot be accomplished in creatures familiar to us because connection between parts is an integral property of living systems. Substances and impulses must be able to move from one segment to another. Yet, in the smallest organisms—and in them alone—substances can move between two unconnected parts by diffusing through membranes of the outer surfaces. Thus, single cells, including all of ours of course, contain organelles lying within the cytoplasm and communicating with other parts of the cell, not by physical connection, but by passage of molecules through bounding membranes. Such structures could, in principle, be designed to rotate like wheels.

The principle that restricts such communication without physical connection to the smallest organisms (or to similarly sized parts of larger organisms) embodies a theme that has circulated extensively throughout these columns: the correlation of size and shape through the changing relationship of surfaces and volumes. With surfaces (length ^{2}) increasing so much more slowly than volumes (length ^{3}) as an object grows, any process regulated by surfaces but essential to volumes must become less efficient unless the enlarging object changes its shape to produce more surface. The external boundary is surface enough for communication between the organelles of a single cell with their minuscule volumes. But the surface of a wheel as large as a human foot could not provision the wheelful of organic matter within. Large organisms must evolve channels—physical connections—to convey the nutrients and oxygen that can no longer diffuse through external surfaces.

Wheels work well, but animals are debarred from building them by structural constraints inherited as an evolutionary legacy. Adaptation does not follow the blueprints of a perfect engineer. It must work with parts available. Yet when I survey animals in all their stunning, if wheelless, variety, I can only marvel at the diversity and good design that a few basic and highly constrained organic patterns have produced. Forced to make do, we do rather well.

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

We couldn't sell our tours for less. So we gave you more.

For 1981, Alitalia offers 36 terrific Italian tours that still give you the best value on the market—only now they're even better than ever.

Despite inflation, our prices for 1981 reflect only minor increases. So in real terms you're actually paying less. And here's how we're giving you more.

We've revised our most popular itineraries to include more features that people said they wanted. Like an excursion to the Swiss resort town of Lugano on several tours. Or two nights in Verona on our "Splendors of Italy". A visit to the Frascati wine cellars on our "Grand Italian." And a side trip to the Villa d'Este Gardens on most of our tours.

We've added a major new 15-day tour called "Rome and the Sunny South" that we think is the best tour of southern Italy ever put together.

We've searched out hotels and restaurants that give you maximum luxury for your lire. And on an Alitalia tour—unlike many other tours—your hotels are always specified and guaranteed in advance.

Our tour groups are intentionally kept small, so you get more personal attention. And Alitalia lets you choose from escorted, semi-escorted or independent tours—so you don't waste money on features you don't really want.

What does all this cost? You can spend as little as $228 for 9 days/7 nights in Rome on one of our "Intermezzo" tours. Or you can splurge on our "Grand Italian," a completely escorted 15-day tour for $850. (These prices are per person, double occupancy, high season—April through October—and are for the finest first-class hotels. Prices are lower for the low season. Airfare is additional.)

For a copy of our beautiful new tour brochure, "Italy loves you," ask your travel agent, or write: Alitalia Tour Department, 666 Fifth Avenue, New York NY 10103.

Alitalia tours. They couldn't be any cheaper. And they couldn't be any better.

Alitalia

AT HOME IN THE SKY

The Seeds of Botany

In 1545, the establishment of Europe's first botanical garden in Padua, Italy, ended centuries of dependence on the ancients and set an example for plant research

by Thomas A. Christopher

To the tourist happily savoring its antiquities, the lovely city of Padua, twenty-two miles west of Venice, seems like an island in time—a place so venerable that it scarcely appears relevant to our modern technological society. Yet on June 29, 1545, one of the seminal events of modern science occurred in this small, northern Italian city. On that date the senate of the Venetian Republic, which then ruled Padua, voted to establish at the University of Padua the first botanical garden in Europe. The unforeseen consequence was nothing less than a revolution in the plant sciences, the awakening of botany from a thousand years of stagnation.

In the sixteenth century Padua was one of the intellectual centers of Europe, the home of a great university with a science faculty second to none. The Renaissance was in full flower, and under its influence, scholars in all fields were throwing off the constraints of medieval dogmatism and making great advances. The University of Padua was particularly noted as a center for botanical learning; in 1533 it had been the first European university to appoint a full-time professor of botany.

That there had not been a single university chair in botany previous to 1533 is an indication of the low state into which the plant sciences had fallen in medieval Europe. As a science, botany hardly existed; what interest there was in plants was purely practical. The only plants medieval scholars had bothered to study were those they believed had economic or medicinal value, and doctors almost entirely dominated the plant sciences. A medieval doctor had to have some rudimentary knowledge of plants since they were the major source of drugs, but even among doctors botanical research was unheard-of. They preferred to gain their knowledge of plants from ancient Greek and Roman texts.

Theophrastus (372?–287? B.C.) and Dioscorides (A.D. 40?–90?) were two ancient Greek botanists whose works were especially influential in medieval Europe; Dioscorides, in particular, was considered the final authority on everything related to plants. Both were fairly reliable sources of information given the limitations of their times. Theophrastus was by far the better scientist, demonstrating in his work keen powers of observation and deductive reasoning. Many of his theories were remarkably accurate and obviously based on the careful study of living plants, both native and foreign. Alexander the Great (356–323 B.C.), on his expeditions to Persia and India, took trained personnel to collect and send back many exotic plants and seeds. Theophrastus was thus able to study Asian plants as well as the flora of Greece; he supposedly maintained collections of foreign plants in his garden in Athens.

Symptomatic of the poverty of medieval plant science, Dioscorides' *De Materia Medica*, which was little more than a handbook of medicinal plants, was in general preferred to Theophrastus' more scholarly works. Worse yet, what real value *De Materia Medica* had was largely overlooked. Dioscorides, while he lacked Theophrastus' energetic spirit of inquiry, did emphasize the importance of fieldwork and the observation of living plants. Medieval scholars, however, chose to ignore this aspect of his book.

The natural result of the absence of primary research during the Middle Ages was that although some scholars were learned in ancient botanical literature, most were surprisingly ignorant about the native plants of their region. The botanical illustrations included in medieval editions of Dioscorides' *De Materia Medica* clearly reflect this lack of knowledge. Many of the plants Dioscorides described can be found growing wild throughout northern Europe, and yet almost without exception the illustrations were mechanically copied from earlier editions of the same book rather than drawn from nature. In this way, each new edition perpetuated the errors of its predecessors and perhaps added a few of its own, so that the illustrations in the editions published toward the end of the Middle Ages bear little if any resemblance to the plants they purport to represent.

Medieval scholars made almost no attempt to investigate the anatomy of plants, their mechanisms of growth and reproduction, or the ways in which they were related to one another. Even the basic concept that different geographical regions have different floras, which Theophrastus had grasped in an elementary form, was not understood. Throughout the Middle Ages, northern European doctors used Dioscorides as their standard reference for identifying medicinal plants without appreciating that many of the plants he described were indigenous to Greece or the Middle East and simply not to be found in England, France, or Germany.

Many of these conditions persisted in the early part of the sixteenth century. Even at the University of Padua, botany was considered nothing more than a branch of the medical curriculum. Although the university did boast the only professor of plant science in Europe, his official title was *lettore dei semplici*, or the professor of simples (simples is an archaic term for medicinal plants).

The professorship was established at the urging of Francesco Bonafede, a professor of medicine. Significantly, Bonafede, considered the best-quali-

Allen Rokach

Left: The Basilica of Santo Antonio seems to watch over the Botanical Garden of Padua University. This eighteenth-century view is taken from a history of the garden written by Roberto de Visiani, director from 1836 to 1878. The garden beds were laid out in a parterre, a geometrical pattern popular in the sixteenth century, when the garden was built. The Botanical Institute, visible at the north end of the garden, houses a library and herbarium. Below: Epinoia, the Greek nymph of Intelligence, shows a mandrake to Dioscorides (right) and Crateuas (left) in this sixth-century A.D. edition of Dioscorides' handbook of plants, De Materia Medica. *The Greek naturalist Dioscorides, who in the Middle Ages was considered to be the final authority on plants, actually lived in the first century A.D., nearly two centuries after the Greek illustrator Crateuas, famed as the best plant artist of the ancient world. Ancient and medieval scholars believed the mandrake, with its resemblance to the human form, had magical and medicinal powers.*

Österreichische Nationalbibliothek

fied applicant for the new position, taught a subject that could be described more accurately as pharmacology than as true botany. Yet, even if he was not a great botanist, botany owes Bonafede a tremendous debt: in addition to securing the establishment of a chair in that science, he was the first to propose the founding of a botanical garden at Padua.

Apparently an original thinker, Bonafede was not satisfied with the traditional academic curriculum. He wanted his students to learn about plants not just from the pages of Dioscorides and Theophrastus but also from the study of living plants. To acquire live material with which to illustrate his lectures and to give his students access to living specimens of the plants he described to them, Bonafede urged the authorities to establish a special garden. In this *orto medicinale*, or "medicinal garden," he planned to cultivate only plants used in the manufacture of drugs.

Österreichische Nationelbibliothek

Above: Their lack of field research and their reliance on ancient texts led medieval scholars to produce increasingly unrealistic botanical illustrations. The chamomile plant shown here, from the oldest known copy of Dioscorides' De Materia Medica *(circa A.D. 512), is drawn in considerable detail. But as illustrators continued to simply copy earlier editions of Dioscorides' work, they perpetuated, and added to, the errors of their predecessors. The renderings of chamomile shown on the following pages demonstrate the decline in accuracy in botanical art throughout the Middle Ages.*

Gardens of medicinal plants were nothing new in medieval Europe. Monasteries often maintained small herb gardens as a convenient source of drugs, and as early as 1447, Pope Nicholas V set aside part of the Vatican grounds for the growing of medicinal plants. What made Bonafede's proposed garden unique was its emphasis on study and research.

In time, Bonafede convinced the university administrators of the need for the garden, and they, in turn, sought the necessary funds from the government. On July 7, 1545, just eight days after the Venetian senate gave its approval, a suitable site, consisting of approximately five acres next to what is now the Alicorno canal, was leased from the monastery of Santa Giustina. Nearly surrounded by the canal, the land was both fertile and well watered. The abundant water supply insured adequate irrigation for the plants and permitted the eventual construction of seventeen fountains and several shallow tanks, which are still used to cultivate aquatic plants.

Francesco Bonafede and his colleagues in the medical faculty had intended the garden to be a teaching laboratory where a collection of medicinal plants would be maintained and a pharmacological museum would be built. In this museum, specimens of the plants grown in the garden were to be displayed, together with samples of the drugs extracted from them. This interesting plan would no doubt have proved an asset to the medical school, but it would not have provided much stimulus for botanical research. Fortunately for the fledgling science, however, the development of the garden was entrusted not only to a representative of the medical faculty, Piero da Noale, but also to an architect from the nearby city of Bergamo, Giovanni Moroni, and to a Venetian aristocrat, Daniele Barbaro.

Whether by good luck or good planning, this triumvirate proved to have a happy combination of talents. While da Noale could speak for the garden's original sponsors, an architect was clearly needed to draw up a plan for the project, and Moroni was an obvious candidate for the job: he was already supervising the construction of the church of Santa Giustina in Padua and had proved his ability on

David Lee

Right: This herbarium specimen from the Institute of the Botanical Garden of Padua University dates to about 1730, some years before Carolus Linnaeus published his system of nomenclature for flowering plants. Below: As the Middle Ages progressed, many botanical texts no longer specified authors and artists. This unattributed chamomile appears in Medicina Antiqua, *an early thirteenth-century anthology that drew upon many herbals, including* De Materia Medica.

Österreichische Nationelbibliothek

that project. Like many other figures of the Italian Renaissance, Moroni was a man of many talents; in addition to being an architect, he was a noted painter and so was able to provide aesthetic as well as technical expertise.

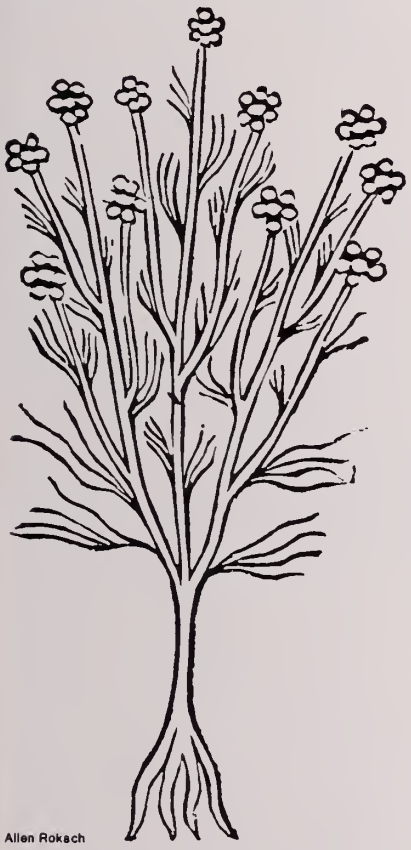
At first glance, Daniele Barbaro, neither a scientist nor a gardener by profession, might seem an unlikely candidate for the third member of the group. As patriarch of Aquileja, then the ecclesiastical capital of northeastern Italy, he held an important position in the ministry of the Catholic church, and his formal role in the triumvirate was to represent the Venetian senate. He was well qualified to assist in the establishment of a botanical garden, however, since in ad-

i
Liliasphodelus luteus

ii
Cana rigata

iii
Calamo aromatico

dition to being an able and energetic administrator, he was a respected amateur botanist with a family prominent in scientific circles in Venice. His great-uncle Ermolao Barbaro, a learned translator of ancient Roman scientific literature, and for many years professor of philosophy at the University of Padua, was one of Italy's foremost authorities on plant science. The senate and the university naturally turned to Ermolao's young relative Daniele when they needed assistance with the garden.



A plan of the garden was soon completed. Moroni was the draftsman, but da Noale and Barbaro, both of whom had scientific knowledge that the architect lacked, undoubtedly advised him concerning the technical aspects of the project. These three men achieved a design that was remarkable for its successful fusion of aesthetic, functional, and scientific elements. The original plan of the garden indicates that the main part was laid out as a perfect circle ninety-two yards in diameter. This circle was divided into four equal parts separated by broad paths, and each of these quadrants was subdivided into a different geometric pattern of small beds. Contemporary fashions in landscape design had influenced how the garden was laid out. Such geometric arrangements of beds, called parterres, were almost invariably prominent features in Italian gardens of this period. This design was also sensible from a practical standpoint since the large number of distinct beds made it possible to grow each variety of plant separately, facilitating the job of keeping the plant collection in order.

The original design of the garden is also interesting because it is hierarchical. Each bed is part of a larger unit, which is in turn part of a still larger unit; the progression continues up to the largest possible unit, the full circle. This suggests that the creators of the garden had some understanding of the hierarchical nature of plant taxonomy and tried to design the garden so that the plants could be arranged according to their natural relationships. Although no accurate understanding of plant taxonomy existed at that time (the present classification system is generally considered to have originated with Carolus Linnaeus in the eighteenth century), attempts had been made as early as the time of Theophrastus to classify plants according to a system of relationships. The founders of the Botanical Garden of Padua University —in particular the amateur botanist Daniele Barbaro—may have intended that the garden be planted according to some primitive taxonomic system. If so, it is the earliest example of a planting scheme that is standard in modern botanical gardens.

By August 1546, work on the garden had progressed so far that a full-time staff was necessary. Initially, the staff consisted of a director and a gardener, but a second gardener was soon added. The gardeners were responsible for the day-to-day maintenance of the garden, while the director supervised its ongoing construction, oversaw the work of the gardeners, and planned the development of the plant collections. For his services, the director received an annual salary of eighty ducats and the use of a house located on the grounds of the garden.

This modest but historic beginning marked the first time since Theophrastus' day that public funds were made available to support botanical research in Europe. Previously, botanists had been dependent for their livelihood on the generosity of wealthy patrons or had pursued their studies as an avocation while supporting themselves by working in another field. Indeed, the pioneering scientists who worked under these difficult conditions accomplished more than might have been anticipated. At Padua, however, botanists were provided not only with research facilities that were unique at the time but also with the opportunity to make botanical research their primary occupation.

The opening of the garden sparked an explosion of scientific activity. The directorship was held by a series of remarkable men who made the garden the admiration of the European scientific community. The first director, Luigi Squalermo, was one of the first Italian scientists to make journeys for the express purpose of collecting and

Above: By the end of the Middle Ages, botanical art had become highly stylized. Since medieval physicians were interested in the uses rather than the forms of plants, there was no need for the chamomile in this copy of Herbarius Latinus, *printed in the late 1400s, to be accurate. Left: Pampas grass, an ornamental grass originally from South America, was introduced into Italy in the middle of the nineteenth century at Padua. Many exotic plants were first grown in Europe at Padua's botanical garden.*

Thomas A. Christopher

First printed in 1491, Hortus Sanitatus *includes a drawing of a chamomile so schematic that it bears virtually no resemblance to the plant it is meant to represent.*

Allen Rokach

David Lee

In the fourth century B.C., the Greek naturalist Theophrastus made careful studies of living plants, including species native to Greece and exotics from Asia. Neglected for many centuries, he is now often called the father of botany.

identifying plants. In an age when travel was expensive and dangerous, he explored France, Switzerland, Italy, Yugoslavia, Greece, and Asia Minor, sending back to Padua many specimens of exotic and hitherto unknown plants. Many of his successors followed his example, notably Giovanni Veslingio, who served as director from 1638 to 1649. Veslingio explored Greece, Palestine, and Egypt and sent a collector to Crete who gathered three hundred kinds of seeds and plants indigenous to that island.

Under the direction of such men, the plant collections in the new garden grew rapidly. In 1552, just seven years after its foundation, the garden contained specimens of 1,500 different varieties of plants; by 1591, the number had risen to 2,000. Although the original intention had been to collect only medicinal plants, the collection soon expanded to encompass many plants of botanical, agricultural, and horticultural interest. Before long, Padua's collection of exotic plants became so impressive that it attracted botanists from all over Europe. Many exotic plants were grown in Europe for the first time in Padua. A number of these plants are horticulturally important today, among them the lilac (*Syringa vulgaris*), rhubarb (*Rheum rhaponticum*), and the black locust (*Robinia pseudoacacia*). And at least one plant introduced by the garden has played a vital economic role: the potato (*Solanum tuberosum*).

During its early years, the Padua botanical garden was also a leader in the field of botanical publications. While serving as its director, Squalermo wrote *Semplici*, in which he attempted to clear up the confusion that had existed throughout the Middle Ages concerning the true identity of the plants referred to by Dioscorides and other ancient authorities on medicinal plants. Squalermo tried to match each plant described by the ancient authors with a plant known to contemporary botany, and the quality of his scholarship was so high that his book was accepted as the standard reference on this subject in the sixteenth and seventeenth centuries.

Many of the earliest botanical descriptions of exotic floras were also published under the aegis of the Padua botanical garden. For example, *De Plantis Aegypti*, a study of Egyptian flora, was published by Prospero Alpino, director of the garden from 1603 until 1616. This book introduced many new plants to European botanists, and although now obsolete, it served as the basis for more complete modern studies of this subject. In 1591, the garden also became the first institution of its kind to publish a catalog and map of all the plants grown in its garden. This kind of reference work is invaluable to any scientist who wishes to study a botanical garden's plant collection, and most botanical gardens now regularly publish plant lists and maps.

The greatest achievement of the Botanical Garden of Padua University, however, was the example it set. Botanical gardens modeled on it were soon founded in other cities, first in Italy at Pisa (1547), Florence (1554), and Bologna (1568), and later outside of Italy at Leipzig (1580), Leyden (1587), and Oxford (1621). Many of these newer research institutes were larger and better endowed than the Padua botanical garden, and by the end of the eighteenth century, Padua was no longer a leader in botanical research.

Padua's botanical garden does not now hold the preeminent place it once did, but it continues to function as a center for botanical research. Now funded by the Italian government rather than by the city of Venice, the garden has preserved its affiliation with the University of Padua and still serves as a learning resource for the university's students. In addition to its collection of live plants, the garden maintains a respectable botanical library and a large herbarium of dried specimens, with a particular emphasis on the plants of the Veneto, the region surrounding Venice.

The garden is by no means a museum, but a special effort has been made to preserve its ties with the past. It still occupies the same five acres leased, and later purchased, from the monastery of Santa Giustina, and a stroll around the grounds with a copy of Giovanni Moroni's plan in hand reveals that the garden's basic design has changed little since 1545. The plant collections have grown and some modern equipment has been installed, but the collections are still planted in beds subdivided in the original geometric patterns. Many of the plant species listed in the catalog of 1591 are still being grown, although in most cases the names have changed.

Throughout the garden, magnificent old plants bear witness to the garden's antiquity. The most notable is a dwarf palm (*Chamaerops humilis*) that was planted in 1585 and was the basis for the first botanical description of this genus in 1720. There are also several enormous old shade trees, some several centuries old. In this setting, which abounds with evidence of a long, rich history, the debt botany owes to this garden and to the modest beginning made there in June of 1545 becomes strikingly clear. □

Allen Rokach

In the sixteenth century, many artists again ventured into the field to study living plants. This chamomile is from Otto Brunfels's Contrafayt Kreuterbuch. *The hand-colored illustrations in this botanical work were arranged by season, reflecting the natural order in which the artist, Hans von Weiditz, came upon the plants in the wild.*

Last Call for the Siberian Crane

A determined captive breeding effort must succeed for this stately bird to rise from the ashes of war

by George Archibald

Two magnificently sculpted cranes stand in the throne room of the emperor's summer palace in Beijing (Peking), China. The pair served the emperors as symbols of long life and happiness. Although the Chinese and other peoples have for centuries painted and sculpted cranes as harbingers of good fortune, the majestic birds could best serve the contemporary world as symbols of crisis.

The status of the Siberian crane (*Grus leucogeranus*) is particularly revealing. This endangered crane, intermediate in size between a sandhill crane and a whooping crane, has a long, powerful beak and, except for black primary feathers and a bright red face, is snow white. Within recent memory, the cranes numbered in the thousands, but as of 1979/80 the species had been reduced to approximately 250 to 300 individuals.

George Archibald; International Crane Foundation

Cranes can be bought at food stalls in Afghan towns, above. Hunting, and the outbreak of hostilities in Afghanistan, could mean the demise of the Siberian cranes that winter in India, opposite.

The attrition of this species has not been a consequence of environmental problems on its breeding grounds, which are vast expanses of sparsely inhabited tundra in Siberia. Rather, the Siberian cranes have been pressed hard by hunting and wetland destruction along their migration routes and wintering range. Now the cranes' precarious hold on existence is threatened by violent political upheavals in the Near East.

Two populations of wild Siberian cranes remain. One group breeds in western Siberia and migrates in two flocks. One flock, numbering nine birds in 1978, winters in the Caspian lowlands, which traverse the northern border of Iran. Although Iran is predominantly a country of mountains and desert, the Caspian lowlands receive precipitation adequate to sustain cultivated crops, forests, and wetlands. In recent years Iran's Department of the Environment, under the inspired leadership of Eskandar Firouz, established several wetland sanctuaries for migratory birds. Ironically, I found the relict population of cranes utilizing flooded rice fields that are part of large duck-trapping complexes.

In an attempt to restock Siberian crane populations that have been extirpated, the International Crane Foundation (ICF), Iran's Department of the Environment, and the USSR Ministry of Agriculture in 1975 began a cooperative program to place Siberian crane eggs produced in captivity into the nests of wild common cranes (*Grus grus*). The hope was that the common crane foster parents, nesting in wetlands in the western USSR, would teach their Siberian crane "offspring" the migration route to wintering areas in Iran. Since the Islamic revolution, however, the future of the foster-parenting project, the status of the relict flock of Siberian cranes, and the fate of the wetland sanctuaries is in question.

The second flock from the western Siberian crane population migrates 3,700 miles to winter at the Keoladeo Ghana Sanctuary in north-central India. These birds breed in one of the least populated areas of the world, and winter in one of the most densely populated. On the way, they stop to feed and rest at a large saline lake called Ab-i-Estada in Afghanistan, before continuing over the Hindu Kush Mountains to India. The cranes are hunted for food during their stopover in Afghanistan. As a result, this flock has declined from seventy-seven birds in 1970 to fifteen in the winter of 1980/81. In 1978 the Ministry of Agriculture of Afghanistan, in cooperation with the U.N.'s Food and Agriculture Organization and the World Wildlife Fund-International, proposed to establish Ab-i-Estada as a nature reserve and provide wardens to protect the cranes from poachers. Tragically, the recent outbreak of hostilities in Afghanistan has thwarted these conservation efforts. During a state of war, the protein packaged in a Siberian crane may spell survival for a tribesman in the backcountry.

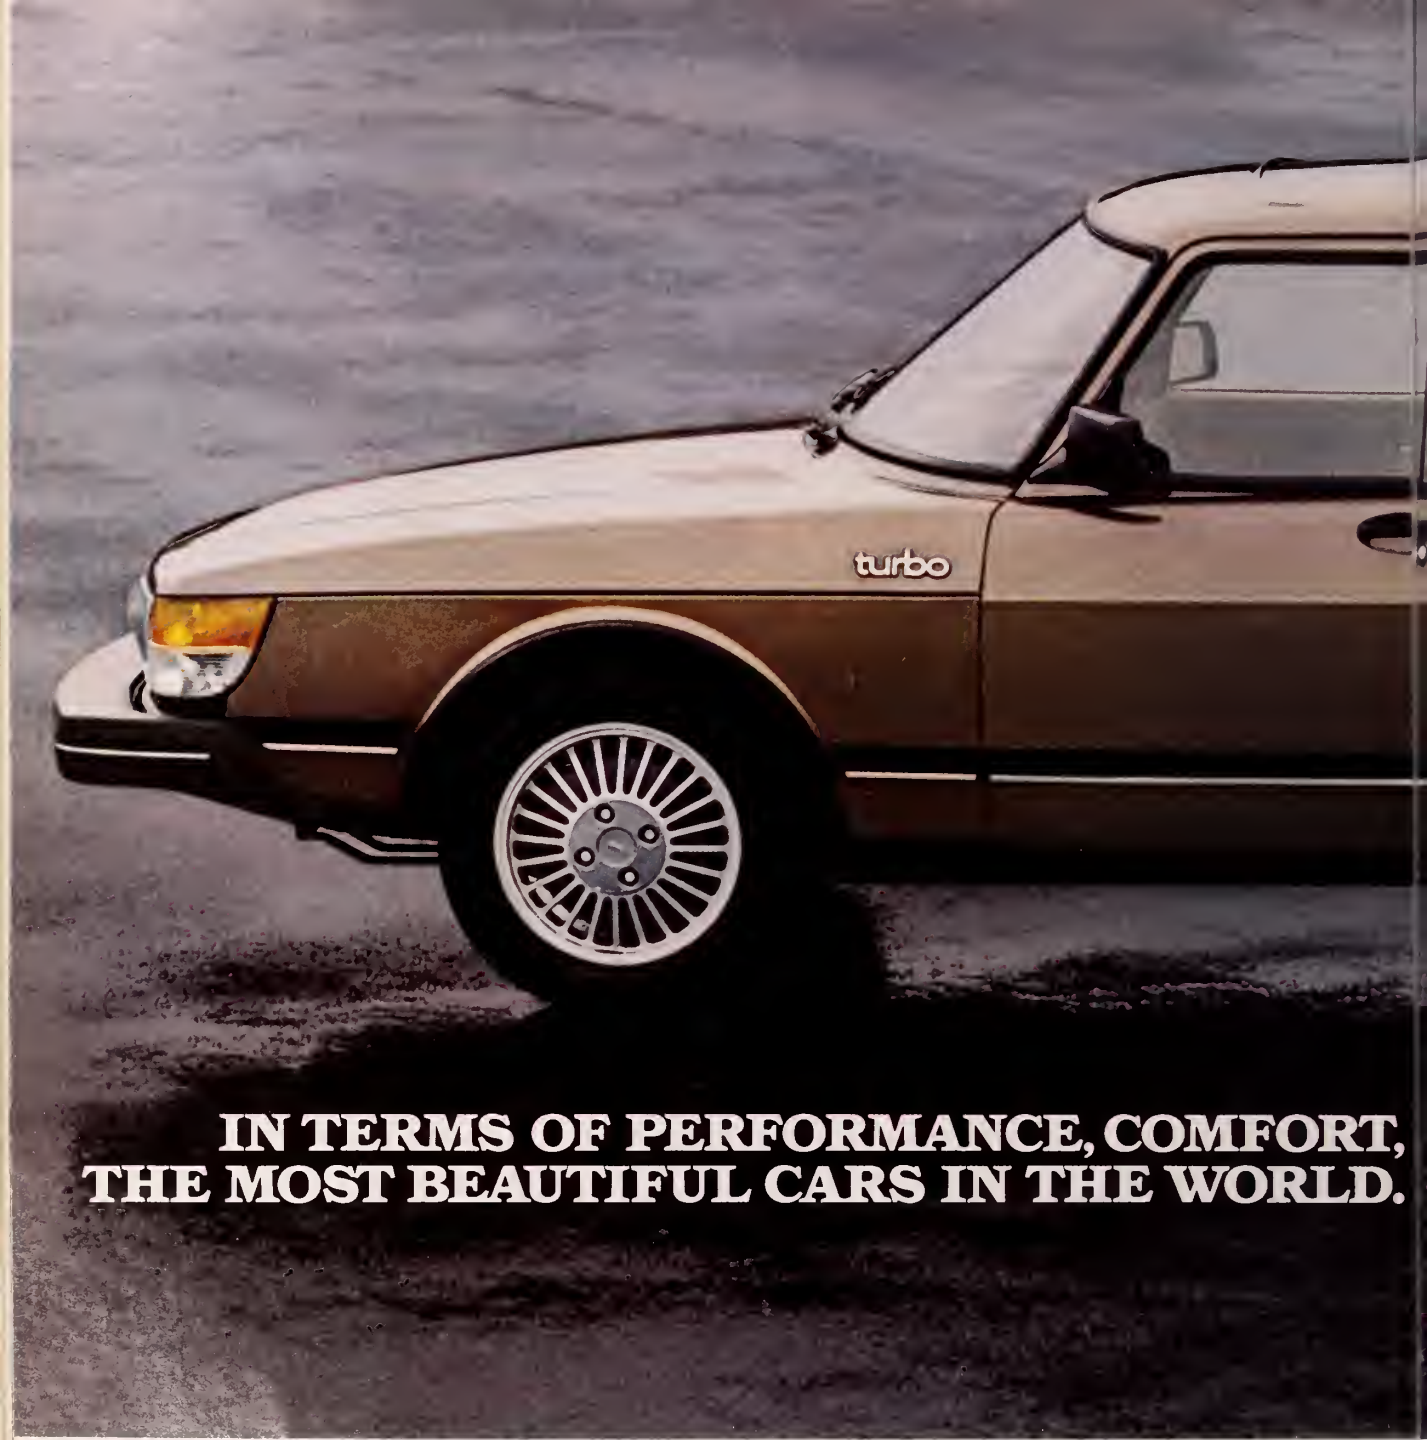
The second, larger population of Siberian cranes, numbering about 200, breeds in eastern Siberia and winters on as yet undetermined wetlands in the basin of the Yangtze River in northeastern China. Chinese ornithologists are conducting ground sur-

Georgo Archibald; Internationel Crana Foundetion

veys to search for the wintering Siberian cranes and hope to initiate aerial surveys sometime this year. But if the wetlands used by this population are flooded by waters backed up from one of the three dams now planned along the Yangtze or if they are drained for agriculture before the birds are found, the prospects for this flock will be bleak.

On the brighter side, the ICF, located in Baraboo, Wisconsin, and the Soviet Ministry of Agriculture have established a "species bank" of captive Siberian cranes. By collecting eggs from the wild, hatching them in incubators, and hand raising the resultant chicks, ICF has established a population of twelve individuals while the Soviets maintain thirteen birds at their captive propagation center in the Oka State Nature Reserve about 200 miles southeast of Moscow.

In this era of environmental and political crises, captive breeding of Siberian cranes may offer the last hope for the survival of the species. When the smoke from the bombs clears, perhaps this great white bird will once again rise to command the skies. □



George Archibald; International Crane Foundation

George H. Harrison

Stately in flight and on the ground, Siberian cranes annually undertake long migrations from their breeding areas in the Soviet Union to their wintering grounds in China, Iran, and in the Keoladeo Ghana Sanctuary in north-central India, below.

IN TERMS OF PERFORMANCE, COMFORT, THE MOST BEAUTIFUL CARS IN THE WORLD.

How dare we call the new 1981 Saab 900 one of the most beautiful cars in the world, what with its wrap-around windshield, pointy front end, sloped rear end and just plain all-around strange looks?

Well, if you look at the Saab the way we do, you'll call it "beautiful" too.

For instance, the outside of the Saab is designed not to make your heart throb, but rather to slice through the wind.

Consequently, the Saab 900 has a low coefficient of drag, which affects performance, handling, and mileage all for the better.

At Saab, *that's* what we call "beautiful."

You may have noticed that Saabs ride a little high off the ground.

That's because we've found that adults like to sit upright in chairs, rather than sit on the floor.

So we provide the Saab with vertical seats that are up off the ground, to give you ample support for your thighs, back, shoulders, to make you as comfortable as is humanly possible. On some models, they're even heated!

And that unconventional windshield, combined with the height of the seat, gives you a phenomenal view of the road.

At Saab, *that's* what we call "beautiful."

Part of what the Saab looks like is a function of the safety features built into it.

For example, if you take away the sheet metal body, you'll see a cage of thick steel beams, pillars, cross members, floor plates, side panels, and so forth.

We call it the Saab "Safety Cage." We designed it to give you and your passengers extraordinary protection in the event of a collision.

Function, not form, was the primary objective in designing the basic shape of the Saab 900.

SAFETY, QUALITY AND ECONOMY, IT'S ONE OF

And, at Saab, *that's* what we call "beautiful."

But if you really want to see how beautiful the Saab 900 is, you have to look under the hood.

Here is the raison d'être for the Saab's very existence.

Regard the lovely, sensuous, voluptuous 2-litre fuel-injected beauty that goes like a 6- or 8-cylinder but does it with only 4.

And if that isn't enough for you, throw open the hood of the Saab 900 Turbo and gaze upon the indescribable beauty of the power plant that will accelerate you and your libido like a 747 on takeoff.

And Saabs give "beautiful" gas mileage. (Saab 900 five-speed Sedan: (21) EPA estimated mpg, 33 estimated highway mpg. Remember, use estimated mpg for comparison only. Mileage varies with speed, trip length and weather. Actual highway mileage will probably be less.)

At Saab, *that's* what we call "beautiful."

If you still need convincing that the new Saab 900 is a beautiful car, the next step is to see one up close.

Right behind the wheel of a moving one would be a good place to take a look.

Because only there can you feel the luxury, the quality, and the beauty of its power, the intelligence of its design.

See the new 1981 front-wheel drive Saab 900 at your Saab dealer today.

And maybe now you'll look at Saab a little differently.

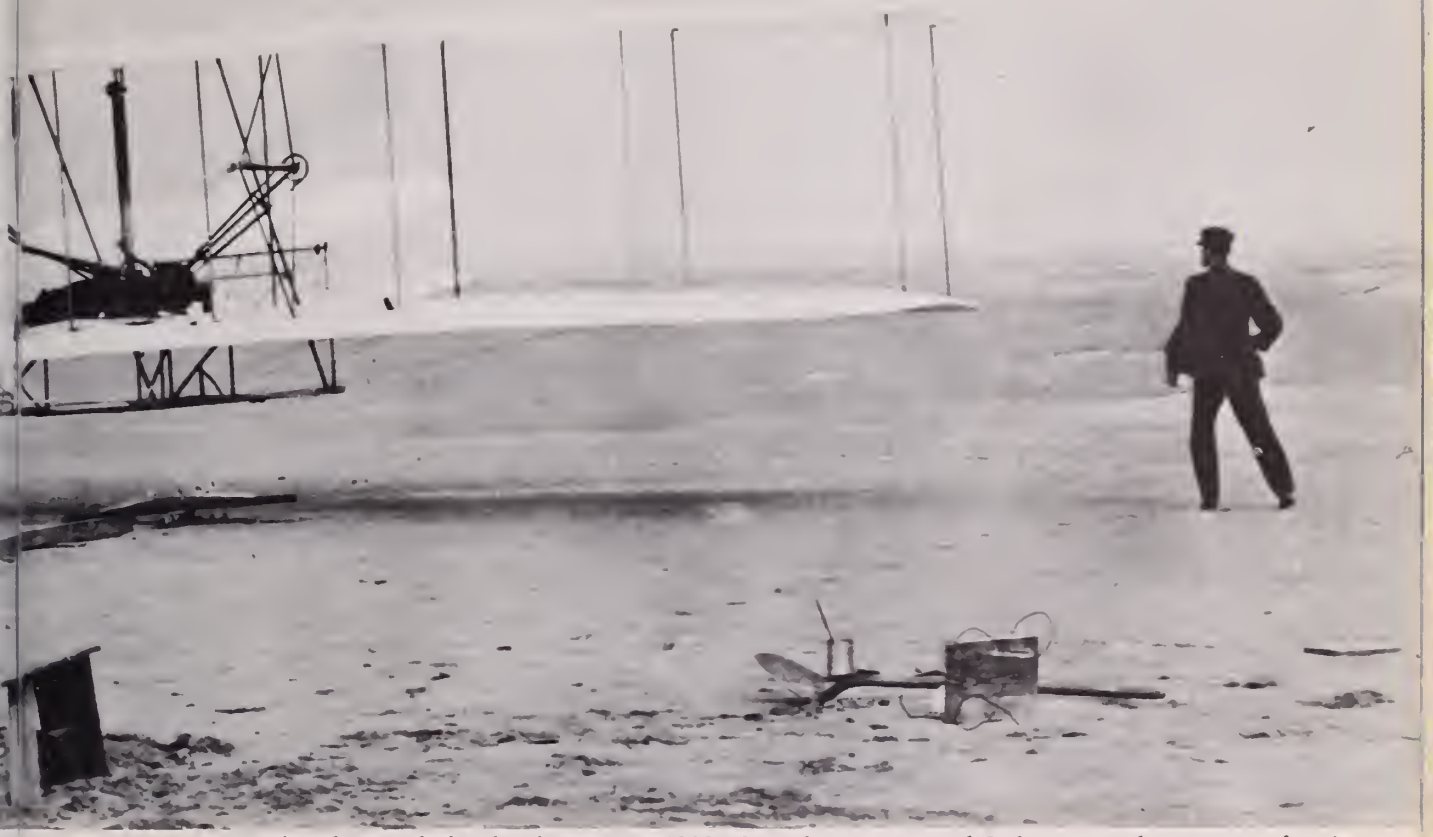
SAAB

The most intelligent car ever built.

The Granger Collection

Genesis of the *Gossamer Condor*

A careful look at soaring birds suggested an innovative path toward human-powered flight



by Morton Grosser

Adapted from *Gossamer Odyssey: The Triumph of Human-powered Flight*, by Dr. Morton Grosser, to be published in April by Houghton Mifflin Company. Copyright © 1981 by Dr. Morton Grosser.

Aviation history was made in August 1977 when a fragile aircraft called the Gossamer Condor *won the £50,000 Kremer Prize for human-powered flight, successfully negotiating a figure-eight course that demanded both maneuverability and sustained flight. Less than two years later, the team that built the* Condor *captured the headlines again with the* Gossamer Albatross, *an improved human-powered airplane that flew across the English Channel. This second airplane will be exhibited at the American Museum of Natural History from March 4 to May 31.*

Tracing the beginnings of the *Gossamer Condor* is like spiraling down through a thermal, diving against the rising column of air to the small circle of warm sand where a minimal twist of wind started the whole thing. For Paul MacCready the circle of sand was probably on a beach in the town of Nokomis, Florida, in July of 1976. The MacCreadys took a family vacation that summer, driving from Pasadena to the east coast of the United States and back in a blue-and-white GMC van. Their route went through White Sands National Monument and Carlsbad, New Mexico, and across the southern part of the country. For the first time in many years Paul MacCready felt relaxed enough to forget his business problems and let his mind float.

One of the subjects that floated up repeatedly was ultralight aircraft. MacCready had just written an article on hang gliders, titled "Developments in Ultralight Gliding," and the subject was on his mind. Although his main professional activity was in meteorology, aviation was his passion. When still a boy in Connecticut, MacCready had designed and built trophy-winning

Long after the Wright brothers' success in 1903, above, human-powered flight remained an aviation frontier.

model planes and gliders. Skilled as a pilot and trained as an aeronautical engineer, in 1953 he was the first American to become international soaring (sailplane) champion.

In the spring of 1976, Doug Lamont, the editor of *Soaring* magazine, had asked MacCready to write an article on hang gliding. It was a diplomatic gesture because the directors of the Soaring Society of America were negative about this new, renegade sport. Lamont hoped that MacCready, as an outstanding member of the soaring establishment, could put hang gliding in perspective for other sailplane pilots. The article appeared just as the MacCreadys were starting their vacation; one of its most interesting parts compared the performance of hang gliders to that of gliding parachutes and soaring birds.

Soon after the trip began, MacCready became fascinated with the large soaring birds he could see through the van's windshield and would stop to scan the sky with binoculars. Anyone who has seen the curving flight of great hawks and vultures across the skies of the American Southwest can understand MacCready's interest, but his motives were not those of the ordinary bird watcher. In 1949 he had read Alfred Woodcock's classic paper on soaring sea birds, and that tour de force (in which Woodcock confirmed a laboratory discovery in fluid mechanics simply by watching birds) had made a deep and lasting impression. On this trip MacCready became convinced that he could make a similar discovery by observation. It might not be like Woodcock's inductive leap into another field of science, but perhaps he could reveal something new about the birds themselves.

Watching circling birds became first a diversion, then a compulsion, then almost the focus of the trip. By the time the family reached Florida, MacCready was stopping the van and getting out to clock the circles of turkey vultures and frigate birds. He also tried to enlist his sons as fellow observers. Parker MacCready, who was 16 that July, remembers his father's obsession vividly: "We thought he was nuts. He kept forcing us to watch birds and estimate their bank angle, and count how long it took for them to do a 360 [degree turn]."

On the west coast of Florida, MacCready had more time to observe circling birds and to sharpen the equations he had been writing in his head. He found that just by estimating a bird's angle of bank, he could—with his knowledge of flight principles—calculate the radius of the bird's circular flight path. By timing the circles, he could also calculate both the actual flight speed and the somewhat higher speed at which the bird would be flying if it flew in a straight line using the same angle of attack (the angle at which the air meets a wing traveling through it).

When equipped with an additional piece of information—the bird's "wing loading," or ratio of weight to wing area—MacCready could go on to estimate the "coefficient of lift." In aerodynamics, that is the quantity convenient for judging how efficient an object with a given shape is at flying. Unexpectedly, the average lift coefficient MacCready arrived at for soaring birds was 0.9, a considerably lower figure than had been reported earlier. When he compared this value to the lift coefficients of hang gliders, he found them surprisingly close. He de-

G. R. Zahm; Bruce Coleman, Inc.

cided that a hang glider, even though relatively inefficient when compared with a sailplane, might conceivably provide a suitable model for the construction of a human-powered aircraft.

On July 14 the MacCreadys visited Kitty Hawk, North Carolina, the site of the Wright brothers' first flights. The next day, en route to Williamsburg, Virginia, Paul MacCready found himself meditating first on bird flight, then on hang gliders, and wondering whether there was "some little hunk of aviation that hadn't been touched yet, something like a super hang glider." Although not as efficiently shaped for flying as a well-designed sailplane, birds are phenomenal flying machines because of the finely tuned control they exercise instinctively. The hang glider cannot offer any such advantage over the sailplane, but its method of construction differs radically. This was the feature MacCready thought to exploit.

A sailplane makes optimal use of rigid wings, at speeds that require a streamlined design. The framework of a hang glider, in contrast, is anything but streamlined, for it is strung with external wires that provide support through tension. Moreover, the surface of its wing, or sail, is shaped partly by the force of air, making it less efficient than a wing with a rigidly supported contour. Despite their drawbacks, however, these design elements of the hang glider permit the use of light construction materials, an advantage that becomes increasingly important the larger a structure is. And it was with a large, light structure that MacCready believed human-powered flight might be practical.

Ultimately, an airplane is supported by the upward pressure of the air on the underside of its wing. Allowing a little simplification, if two airplanes weigh the same amount and have wings of quite different sizes, the one with a much bigger wing is likely to be a "floater," and the one with a very small wing will probably be a "sinker." More precisely, an airplane falls slower if each unit of wing area has less weight to support and faster if it has more. If the sinking speed of an airplane is low, it can be kept aloft by an engine that supplies power at a relatively low rate. In addition, the lighter the airplane, the lower the power required. In an ideal situation, where all the power supplied is used to generate lift, the power necessary to fly is simply equal to the weight of the aircraft multiplied by its sinking speed.

MacCready calculated that a reasonably efficient hang glider carrying an average pilot weighs about 200 pounds and has a sinking speed of approximately 4 feet per second when flying in still air. Under these conditions, the minimum power needed to keep the glider aloft would have to be supplied at the rate of $4 \times 200 = 800$ foot-pounds per second, or 1.45 horsepower (one horsepower equals 550 foot-pounds per second, or 746 watts). MacCready reasoned that if you could triple all of a hang glider's dimensions and keep its weight about the same by using very light structural materials and external wire bracing, then the sinking speed would be decreased to one-third of its former value. That meant that such a giant hang glider would fly on only a third of the power used by a standard hang glider: 1.45/3, or 0.48 horsepower. Supplying this amount of power is within the range of human capability. (An "average fit person" can supply

Soaring birds, such as the red-tailed hawk, above, are less efficiently shaped for flying than once assumed.

up to 2 horsepower in a brief burst and can sustain about 0.25 horsepower over an indefinite period of time.)

Tyler MacCready remembers the ride to Williamsburg as "hot and buggy." His father remembers it as "pleasant," even including the interminable Beatles tapes and Monty Python skits. By the end of the day the crucial connections had come together: MacCready was sure that a human-powered airplane could be built by using hang glider technology. He didn't think the visit to Kitty Hawk had influenced him.

If every inventor in history who thought of building a human-powered airplane had actually built one, we would probably have run out of airport space long ago. In Paul MacCready's case, the motive for converting his private hypothesis into a major project was partly financial gain. The £50,000 ($86,000) Kremer Prize was being offered for the first human-powered flight around a figure-eight course that met a number of specifications concerning altitude, distance, and turning. To MacCready, the Kremer Competition was a chance to tackle a fascinating problem and possibly pay off some of his business debts at the same time. The combination was irresistible. Soon after he arrived home in Pasadena, he built what might be called a nestling: an eight-foot-span, thread-braced balsa wood and tissue model of the airplane that would become the *Gossamer Condor*.

To understand MacCready's concept, it is necessary to know how a hang glider is built. In 1976, the majority of hang gliders being flown were versions of the triangular, flexible wing glider patented by California engineer Francis M. Rogallo and his wife, Gertrude, in 1948. Because of the shape of the fabric sail, the visual impression of a Rogallo hang glider is that of a broad triangular arrowhead flying point forward. Only when the covering is removed does the fundamental shape of the frame become clear. It is really a three-dimensional cross, like a child's jack.

In a typical Rogallo hang glider, the keel tube runs fore and aft, parallel to the direction of flight. The crossbar, about sixteen feet long, runs horizontally, at right angles to the keel, and the two members are joined where they cross. Standing straight up out of this central main joint, perpendicular to both of the other frame components, is the king post, and directly below the main joint is the yoke, or control bar, which can be considered a divided downward extension of the king post. Bracing wires connect the tips of these members, and if the wires are rigged tightly, a rigid structure results. A model of the frame looks like a diamond crystal or like two pyramids joined base to base.

The two leading-edge spars that form the characteristic A-shape of a Rogallo wing are superimposed on this basic frame. Spanning about twenty-four feet, they are joined at the front of the keel and fastened to the ends of the crossbar, which serves as a transverse brace. Stripped of its skin, a Rogallo airframe looks more like a structural art project than the skeleton of a flying machine. It is unrecognizable as a relative of the elegant and highly developed sailplane.

In recent years the shapes of hang gliders have changed and diversified in a search for lower sink rates and better control. MacCready predicted this evolution in a paper he presented to the Soaring Society of America in

Frank J. Miller, Photo Researchers

1975, but the structure he visualized for his human-powered airplane was based on the x-y-z frame of the classic Rogallo hang glider.

The structure can easily be seen in the *Gossamer Condor*. The main airframe joint is still in the same central position, with the king post extending above it and a bottom post replacing the hang glider's control bar below it. The keel, as before, lies along the line of flight, but its forward end droops, becoming a bowsprit to support a stabilizing control surface. The most dramatic change is in the crossbar; from a modest brace, about 16 feet long in a standard 24-foot Rogallo, it has grown to the 96-foot main spar of the *Gossamer Condor*'s wing. Although the frame members are not truly orthogonal—the wings were eventually swept back nine degrees to adjust the center of gravity—a child's jack is still evident at the center of the *Condor*'s skeleton.

The decision to use this structure for a human-powered plane was an inspiration, but by itself a lightweight structure is not a guarantee of success. Like any object that must conform to the laws of nature, an airplane is a set of interlocking compromises, some of which have a higher priority than others.

MacCready had determined early on that a very large wing was important to reduce sinking speed. He eventually calculated that for a pilot to fly his hypothetical human-powered airplane any great distance, the sinking speed would have to be a quarter of the value for a hang glider. Allowing some realistic increased weight for the much larger structure, MacCready estimated that the projected human-powered aircraft would need nearly 1,000 square feet of wing area to provide an adequately low sinking speed.

Long, narrow wings are more efficient in most flight regimes than short, wide ones. The area and shape requirements predicted a wingspan of nearly 100 feet for MacCready's airplane. Such long wings would require an intricate web of external bracing, hundreds of feet of exposed, drag-producing wire—a prospect that would make a designer of conventional airplanes shudder. In order to fly, a plane must sustain a balance between the paired forces that act on any flying object: its lift must be equal to the pull of gravity and its thrust must be equal to its drag. There is not much thrust to spare in a human-powered aircraft.

In aerodynamics, drag is divided into two kinds: parasite drag, which is caused by the frictional resistance of air to things moving through it, and induced drag, which is the energy price the wing pays for generating lift. Since airplanes must generate lift in order to fly, designers usually try to reduce parasite drag to a minimum by streamlining and eliminating friction-producing structures. Their aim is an aerodynamically "clean" plane, which in this case seemed impossible. The only option was to fly very slowly, so that parasite drag would be low, and to depend on the big wing to provide enough lift.

MacCready probably did not realize at the time how much his own background had conditioned him to accept a wire-braced airframe. He attributed it to hang glider design, but the designers of other Kremer Prize contenders were also aware of hang gliders. Almost all of them, in different parts of the world, chose to build

The hang glider, with its wire stays and nonrigid wing, provided a model of light construction for the Condor.

streamlined, cantilever-wing monoplanes—aircraft that looked like propeller-driven sailplanes. It is a safe bet that if other designers had been offered plans for the *Gossamer Condor,* they would have rejected this primitive, wire-festooned aircraft with amusement and disdain.

No doubt, MacCready's experience building wire-braced model airplanes influenced him. He was also familiar with early full-size airplanes that had wings braced with exposed wire stays radiating from a king post. In fact—ironically—some of his open-mindedness toward the *Condor*'s structure can be attributed to his isolation from current airplane design. Since taking his Ph.D. in 1952, he had had almost no direct involvement with aeronautical structural engineering. Unlike other designers of human-powered aircraft, he was able to concentrate on the problems of flight without the need to produce a "modern" vehicle. Certainly the original sketches for the *Gossamer Condor* contained more of MacCready's past than of aviation's present.

In the beginning little more than the huge wing and bracing booms were envisioned for the plane. MacCready wanted to use as few components as possible to keep the airframe light. He hoped to stabilize the plane in pitch —fore-and-aft rotation about the wingspan axis—by placing the pilot well below the wing where his weight would act as a pendulum stabilizer, a technique still used to control some flying scale models.

Between August 10 and August 20, 1976, MacCready built a second balsa model of his design. A block of wood and some modeling clay represented the weight of a pilot at the base of the bottom post, and the wing was covered only on its upper side, again like an indoor model or a hang glider. (Later on, the design evolved to include covering on the underside of the wing as well.) The models had bowsprits carrying small stabilizers, but the first test glides showed that they were unstable in pitch.

At this point MacCready asked his friend and colleague Peter Lissaman for some advice about stabilizer size, and the nucleus of the "Gossamer Squadron" was formed. Although most of his work was concerned with large aircraft and fluid mechanics, Lissaman knew all about the Kremer Prize. When MacCready broached the giant hang glider idea, Lissaman was skeptical: "Lots of people have tried lots of technology." Still, it took him only a few moments to calculate, on the back of the proverbial envelope, that the pendulum effect of a pilot's weight would not provide enough stability in pitch; a fair-sized external stabilizer was needed.

The second model was soon fitted with a larger stabilizer and test glided successfully. "Oh, it flies backward!" the *Condor* and *Albatross* teams would become used to hearing from nonaeronautical observers reacting to the stabilizer's forward position. But this feature, known as a canard stabilizer, did not look unusual to MacCready, who had used it many times on the models he had built as a boy. It even flew. "Not a brilliant model," MacCready says, "but good enough to convince me that it was worth while to go ahead."

MacCready called his brother-in-law Kirke Leonard and announced, "I'd like to build a human-powered airplane." Leonard thus began adding his years of engineering experience

Don Monroe

and craftsmanship to the project. Within a few days the two were drawing templates and building the first wing ribs for a prototype that was to have a wingspan of eighty-eight feet—one foot less than a DC-9 Series 10 airliner. A few quick measurements showed that the plane would have to be assembled in a larger space than they had available. While aluminum tubing began to be shaped into frame members, a search for a hangar began, and MacCready recruited a fourth teammate, a soaring and hang-gliding enthusiast named Jack Lambie.

The hangar search turned up a temporary assembly site: the Rosemont Pavilion, a large building used during the construction of the mobile floral displays for Pasadena's annual Tournament of Roses. The one drawback was limited time; the building would be needed in a few weeks to begin preparations for the Rose Bowl Parade. MacCready decided to try it anyway. The materials were moved in on September 2, and for the next ten days Jack Lambie, Kirke Leonard, and Paul MacCready sawed and drilled aluminum tubing, while Peter Lissaman verified calculations.

Most of the plane's components were "lofted," or laid out, full-size on the floor, using chalk, tape, and paper templates (a method used three years later on the successor to the *Gossamer Condor*, the *Gossamer Albatross*, which flew across the English Channel). The wing spar was assembled from eight lengths of two-inch-diameter aluminum alloy tubing. There were only seven thin aluminum tubing ribs, and they were weighted with water bags to simulate flying loads while the bracing wires were rigged. The covering was Du Pont Mylar, a transparent polyester film.

Anyone who has worked in the aerospace industry can only smile at the thought of four men proposing to build an 88-foot-span airplane in ten days. It is too funny to even argue about. And yet MacCready even anticipated that the whole *Condor* project could be completed in six weeks.

In fact it took fifty-two weeks, almost to the day; but the first prototype, astonishingly, was completed on schedule. Ten days after the team started assembling the trial plane upside down on the floor of the Rosemont Pavilion, it was ready for glide tests. It even had a name. In several MacCready family conferences *Condor* had emerged as the prime candidate because of the California condor's rarity, ungainliness, and great wingspan. *Gossamer* was added because of the plane's fragility and lightness, and also, as Parker MacCready says, "Because it sounded right."

Paul MacCready was away on a business trip on September 14. When he returned at 8:30 that evening, it was to the news that the project would be losing most of its space the next morning and would have to be out of the building completely by the afternoon. He decided that they should finish the plane and fly it that night. It took three hours to cover the wing-tip rudders with Mylar, connect their rubber-band centering controls, and attach the last few wing wires.

Just after midnight Paul and Tyler MacCready, Kirke Leonard, Jack Lambie, and several friends and relations eased the huge plane out to the Rose Bowl parking lot and turned it right side up. There had been heavy ground fog all evening, and now the fog turned to a fine drizzle. The crew

Space-age materials were needed to build the Condor *and its successor, the* Gossamer Albatross, *above.*

lined up a few cars and turned their headlights on. It is tempting to imagine what a passerby might have thought of this fragile dragon with its aluminum skeleton and plastic skin shimmering in the lights: the embryo of an airplane.

The first job was to weigh the plane. MacCready had calculated its empty weight as forty-two pounds, but rainwater was already building up on the wing surface, and the first weight was fifty-eight pounds. While the team watched, the one-inch-diameter king post bowed more and more under the weight of the water, and then buckled. They hurriedly replaced it with a 1.5-inch diameter tube and rerigged the stays. MacCready decided to try glide tests in a grass parking field for the Rose Bowl, and the now-sodden group trundled the plane on a dolly across Seco Street to the field.

For the next two hours the team slogged back and forth on their makeshift runway. Crew members steadied the *Condor*'s wing tips and bowsprit while MacCready held up the bottom post and tried to control the pitch angle with a clothesline attached to the stabilizer. By 1:00 A.M. the plane weighed eighty pounds, and all the participants agreed that an hour later its original weight had doubled.

Finding agreement on what else happened that night is more difficult, an aeronautical *Rashomon*. Kirke Leonard was the most disparaging: "It was a very foggy night, and the fog turned to rain and condensed on the wings. There wasn't any head wind, but when we tried to run, it wouldn't fly at all. It never got off the ground."

Jack Lambie only saw the good parts: "Although the rain added a lot of weight, it was apparent that the craft was more like a balloon than an airplane. We walked with it at five miles per hour and it lifted easily, straining at the ropes we attached to the corners. Nothing broke in the flight tests."

For MacCready, despite the problems, the test was a confirmation of his theories. "I mainly wanted to see whether the structure would work, and if the canard stabilizer would control the pitch. It did that, maybe not perfectly, but enough so that it was worth going on. When the wing lifted, I hung on and became convinced that the design was what we had hoped for."

By 2:00 A.M. the crew had made ten test runs. In his notes on these "flights" MacCready referred to the wing as a sail; the design was still an ultralight hang glider in his mind. On their way back to the Rosemont Pavilion the team discovered one of the drawbacks of an ultralight hang glider. As they crossed Seco Street, headed northeast, a gusty tailwind hit the plane. The trailing edge of the wing bent down sharply, the right wing snapped at the inboard joint, and then at others. A few moments later several ribs buckled, the right wing tip broke off, and tears began to spread across the Mylar covering. The scene was ludicrously similar to the old films of human-powered flight attempts that are shown as real-life cartoons.

The team dragged the remains into the pavilion, disassembled them, and moved them into a storage bay. At 2:20 A.M., the prototype *Gossamer Condor* was a pile of bent aluminum tubing, wire, and bedraggled Mylar that, in fact, had never flown at all. The next morning it was trucked up to Mojave Airport, to be made into the human-powered aircraft that would win the Kremer Prize. □

Vermont Country Calendar

Town-meeting day is often the first day of mud season

by Eleanor A. Ott

Richard W. Brown

Lifelong Vermonters and newcomers from out of state attend the local town meeting.

Most of what I've learned about Vermont living I learned in Lucille Cerutti's kitchen. Lucille and I met at Goddard College, in Plainfield, Vermont, where I teach folk studies and she runs the Community Services office, helping students solve their personal problems. Lucille, like her parents, has lived in this rural Vermont area all of her life, and her special heritage colors her daily encounters with students as well as neighbors. I received my first lesson in country ways from Lucille the day I bought half a pig and she came out to my place to help me deal with the head. The result, hog's head cheese, is not unique to Vermont. It is simply part of the traditional way of living that is still found in Vermont's rural villages. In these rushed times, life in such a village is a rare experience, rich and coherent. Because of Vermont's extremes of weather, each activity, whether work or play, has its season. As Lucille has helped me to know, the passage of the months creates a satisfying cycle of country living.

Town-meeting day, the first Tuesday in March, is often also the first day of mud season. At least this is the first day that, despite high snowbanks and four feet of snow still in the woods, we really notice the mud. There is no doubt the gravel roads are beginning to thaw. So are the people, who steam up the windows in the frame meeting hall that was once the Gospel Hollow Congregational Church. The meeting begins when Sidney Liff raps his gavel, and the discussions are joined not only by Vermonters from way back, but also by newcomers like me: folks from "down country," or out of state.

The town meeting is both a political affair and a social one, a mixing of life styles and generations. Last year Eva Morse was reelected town clerk, demonstrating that women have their voice and function in town affairs. Yet it is the women who slip downstairs late in the morning session to lay the tables and set out the casseroles of food brought by townspeople for the meeting-day dinner. Each year we sit at long tables, passing around the bowls of home-baked beans and brown bread. Last year I found to my right 85-year-old Neil Converse, at his prime judged the best fiddler in the Northeast; on my left sat the new woman minister for the town's two churches.

It is no accident that town-meeting day marks the beginning of the Vermont year. This is the time when the season changes. Mercifully, winter has given people time to be idle, to knit by the fire, to make soup, to work jigsaw puzzles, to visit. But with the first days of above-freezing temperatures, as the sun melts back the snow to create ice jams and mud, the pace of life changes radically. In fact, town-meeting day comes none too soon. There are trees to tap, buckets to hang out in the woods, and then the sap must be collected and boiled into maple syrup. It's a matter of timing, of seizing chances as they come. By necessity, the work of the day must be attuned to the sun, the wind, and the weather.

As the sap rises with the first spring thaw, the task of tapping the maple trees gets under way.

Nathan Bann; Woodfin Camp

Lucille describes how sugaring was done when she was a child:

> We used to gather sap in wooden buckets. If you think aluminum buckets are heavy, you should have carried wooden ones. We tapped some 500 trees every year, and on a good day we might empty each of those buckets two or three times. Sometimes a season can last off and on for four or five weeks. And before that we had chopped and hauled the wood to burn in the evaporator to boil the water out of the sap, forty gallons of sap for each gallon of syrup. It wasn't like there wasn't anything to do.

If you don't sugar yourself, you at least stop by to visit while sap is being boiled down at a sugarhouse. Accord-

Nathan Benn; Woodfin Camp

ing to Lucille, "It's a smell you never forget—boiling sap, wood smoke, and sweaty old men." If the weather is just right and the sap is running steady, the fires and the evaporator may be tended round the clock. Visiting for a bit breaks the monotony, and you almost always get to have a taste of new syrup. "What I like to do best when they're boiling," Lucille continues, "is to take an egg, crack it lightly, and put it down in the boiling syrup in the first section of the evaporator, letting the egg ooze a little out along the shell and the taste of the syrup get into the egg. Is that good!"

Sugaring goes on, in fits and starts, during March and April, as long as the nights drop back to below freezing and the days have sun and get warm. Then the frost really comes out of the roads, the culverts collapse, and the spring rivers appear. One always runs down the middle of the road in front of Andy Scott's house, and for several weeks a wide swath of water rushes behind Forest Davis's barn. Sugaring comes to a climactic end with a sugaring-off party.

Maple sugar is made by boiling maple syrup until it reaches the right temperature and then by stirring it and beating it until it reaches the right graininess and consistency. There's never enough maple sugar, so making it is an event, almost always marked by a celebration. In the past, people piled into the sugarhouse for the sugaring-off party, but today they come more often to a farm kitchen to eat the hot syrup and maple sugar poured

Costa Manos; Magnum Photos

over bowls of fresh snow. They cut the sweetness with sour or dill pickles, set aside for this purpose when pickles were being put up in the fall, and fill up on doughnuts. The sugaring-off party used to be a big neighborhood gathering to which all the women brought homemade "plain doughnuts." "Now you might ask," grins Lucille, "what is a plain doughnut? Is it a raised doughnut or one that is made with biscuit dough? The fact is no two women's doughnuts are the same, and each of us jealously guards her own way of making them." And fifty years ago, potent sap beer was passed around more than now. This beer takes only two weeks to make from sap and hops: "It's clear like champagne. But don't be fooled," Lucille cautions. "If you drink more than a little glassful, you don't move."

During the worst of mud season a deceptive mud hole appears in front of Lucille's house on Hollister Hill. When her youngest son, Dean, was a teen-ager, he used to sit in the yard with a collection of old fence posts, planking, and big stones waiting for a car to come along. People would drive up to it, get out, stand and look. They'd even discuss the prospects with Dean. Often they would turn around and drive away, but sometimes they would say, "Oh, I can make it." Then Dean would sit and wait, and when the wheels were disappearing in the mud, he would move down the yard to help the driver drop in stones and lay the boards. Almost no car could run the hole alone, and no one accepted Dean's help without giving him a dollar or so. It was reliable mud money.

"Sugaring," Lucille explains,

is over when the peepers sing. That is the beginning of spring. Or when I go out on the porch in the morning and hear the first redwing. It's a wonderful sound. Before spring comes we want so much to taste fresh fish that we fish through the ice for anything. One day my husband, Sil, and I caught seventy-four fish through the ice, and when they were all cleaned, they weighed only two and a quarter pounds. But we ate them, they tasted so good. Some Woodbury people go smelting; there are smelt in Nelson Pond. The smelt go up the creek by Cranberry Pond. But it's time for perch fishing when the apple blossoms just begin to open. You know it's spring when you're able to open all the doors and windows and let the air in, when you look out over the countryside and see a rose-colored hue over the whole side hill.

After town meeting and sugaring, and up to Memorial Day, one of the main chores is going into the woods, where the ground is still frozen but most of the snow is gone, and cutting down next winter's wood. Later in the summer these logs will be hauled out, sawed, split, and stacked. It's getting to be more and more like the old days,

After the sap has been boiled down in a sugarhouse, left, the new maple sugar and syrup are enjoyed on bowls of fresh snow, lower left. Firewood, below, remains an important fuel, at least for auxiliary wood stoves.

Richard W. Brown

Richard W. Brown

Memorial Day is fittingly observed.

when everyone depended on wood for fuel. This is also the time when everyone is getting ready to plant.

"Before gardening really gets rolling,'" Lucille points out,

there are the repairs from winter: always some board off the porch or roof, cleaning up the mouse trash, lawns to rake after the moles, and the tilling to do. The partridges come and eat the buds off the poplars and scrub-apples on the side hill. Even as recently as when I was a child, this time between sugaring and putting in the garden was the time for getting the haying equipment ready. Then the machines were almost all pulled by horses. We would sharpen the knives on the mowing machine, grease the mower and the dump rake, and check to see that the wooden handles on the hay forks were in good condition. Since the horses had been busy all winter hauling wood, their harnesses usually needed repair.

As early as possible, Lucille's husband, Sil, works the soil in a little, protected garden and plants a little of everything that won't be killed by frost: beets, carrots, dill, lettuce, parsley, Swiss chard, peas. The main garden he plants later, on Memorial Day weekend. Sil works as a granite-stone cutter, and since he is on a night shift, he is able to work in the garden each day. "You got to have peas by the Fourth of July," insists Lucille, "so you got to plant them as soon as you can." On Memorial Day Lucille and her mother take flower wreaths to the cemetery. Some years, if it warms up quickly, Memorial Day is the beginning of black-fly season. "Sometimes the black flies get so bad, Grandma even gets to smoking cigarettes."

Sil buys seeds, onion sets, and seed potatoes in bulk from Clark's Feed Store, where he used to work. He buys enough for the whole family, for four gardens besides his own. Not more than ten miles away live Lucille's parents—Grandma and Gramps—and Lucille and Sil's three married children—Judy, Inda, and Moe—with their families. (The younger son, Dean, lives in Idaho.) Everyone takes what they need from the common seed supply. Moe and Dean used to be the ones who would help their grandparents, shovel snow off their porch roof, help dig up the garden. Now Judy's boy, the oldest great-grandson, takes care of those tasks.

Both Lucille and Sil were raised in northern Vermont. Lucille Wheeler grew up in North Montpelier and Plainfield. Her ancestors came to Vermont in the 1700s, moving north to the wilderness from Connecticut. Silvio Cerutti's father was a stonecutter from Italy who settled in Barre and worked in the stone sheds. Sil was born on a hill farm and grew up with a strong sense of his Italian heritage, eventually taking up his father's trade. Lucille and Sil have raised their children in both the New England and the Italian traditions, and all their family celebrations reflect a marriage of the two cultures.

One of the main family gatherings takes place during spring, at Easter. The whole family always goes to Lucille's parents, "to Grandma's," for Easter breakfast. The family gathering includes a few old people in town who have nowhere else to go. There's ham and eggs, and Lucille and her daughters have made hot cross buns. Everyone brings colored eggs and hides them. Each of the children takes a small straw basket, from a collection stored from year to year, and goes to gather up the eggs. All of this occurs early on Easter morning, since some in the family go on to church.

"The center of the family," explains Lucille,

was my mother and her home. As children we were always there for any holiday or special occasion. After Sil and I were married we were there, we went back there as home. Then as my children got older and my parents got older, gradually it was that my children and my parents came to my home. Now my children come with their own children. It's that way for almost every occasion except Easter breakfast and Christmas breakfast. Those are special times, and we always go to Grandma's.

The first robin, the first dandelion greens, the first radishes: every year the order of these beginnings is observed, and each bird, wildflower, and garden plant accounted for. In one patch of woods past Walter Smith's barn, beyond his sugarhouse, all the wildflowers appear in rapid succession. The tiny, insidious black fly takes its place as well. They say that when some down country speculators were nosing around to buy the side of Spruce Mountain for development, local folk showed them into the woods to survey during black flies, and they never returned. The flies can cause fever, itching, and pain. Lucille tells of the time, back when men's pants had buttons rather than zippers, that Sil went fishing during black flies and was bitten so badly, she had to sit him in baths of baking soda. It is during black-fly season that gardens go in and weeds begin to grow. And it is invariably during this time that dandelions are picked for dandelion wine. By the Fourth of July the flies are gone and the peas have come.

"You have peas and johnnycake with salt pork," relates Lucille.

You fry the salt pork until it's transparent, put in the first little new potatoes, peas, and top cream. You can do the same thing with little new string beans. And johnnycake, that's made with cornmeal. You think about it all winter when you're going to the garden and digging up parsnips and horseradish.

Plainfield, with its population of 952, plus the college community, celebrates the Fourth of July in a big way, with a parade, a chicken barbecue, and fireworks. With games, concession booths, a horse show, and an auction, the activities go on all day. "Even though the relatives from down country Long Island always

Nathan Benn, Woodfin Camp

Draft horses display their strength during summer festivities.

come," says Lucille, "it's more of a civic, or town, event than a family thing. People come back you haven't seen for a while; the town's always chock-full of people."

Actually, the planning for the Fourth of July celebration begins in January or February. A committee of local people orders fireworks, toys and games for grab bags, and several hundred chickens, and arranges for the auctioneer, the booths, and the horse show. As the day approaches, Walter Smith rubs down his ruddy Devon oxen team and the children from Maple Hill Community School make costumes. For the Bicentennial they portrayed characters from the *Wizard of Oz*. (That year the parade made the cover of *Life* magazine. Bread and Puppet Theater figures of fantastic, white-winged birds, twelve feet wide, floated under the telephone wires, and Uncle Sam danced down the hill on ten-foot-high stilts.) The parade also features Norman Dix and his rubbish-removal truck, the college's 1942 fire engine, a two-fronted car, and all the horses and bicycles in town. Even though Lucille and her daughter Judy spend most of the day in the kitchen of the village firehouse stirring vats of *mostaccioli* sauce, they never miss the parade, the Shriner calliope, the clowns. After dusk the ballfield fills with kids and cars and mating fireflies, and fireworks exploding at the edge of the bordering woods end the day.

There are never enough hours in the days of summer. Vegetables continually need picking. Lucille still puts up green and yellow beans in Mason and Ball jars. In the days before every family had a big freezer in the cellar, not only were all the different vegetables canned but chicken and beef as well. At the end of the summer it was not unusual to have 400 jars on the shelves that lined the cellar, each food in its special place. "You canned in a great big copper boiler," explains Lucille, showing its size with her arms. "You could fit fifteen quarts in the boiler if you mixed square and round jars, but only fourteen if they were all round."

The canning was not such a tedious job—many hands really did make lighter work. They still do, of course, but freezing is a lot easier than canning. The Rural Electrification Administration brought electricity into most of Vermont's rural areas in the 1930s, and freezers arrived about twenty years ago through the Washington County Electric Co-op.

Beginning with the first new moon in July, if the weather's been right, if there was enough snow cover all winter and June was not too dry, the boletus mushrooms grow. Sometimes these mushrooms are as big around as dinner plates, all shades of leathery brown on a firm stem. Their growing places are guarded secrets. Mushrooming is a passion, particularly of the Italians, as well as some of the French Canadians. For the thirty-odd years Lucille and Sil have been married, they have gone mushrooming. The whole family goes, carrying large burlap bags up the side hills.

"You lift up a spruce bough," Lucille chuckles,

and the ground is covered with mushrooms. You fall to your knees, spruce needles scratching down your neck, and pick as fast as you can. You get so excited, no matter how many times you've done

Richard W. Brown

it. You cut them off with a knife, cleaning as you go, filling the bags to bursting. Boletus comes in a growing moon in July, August, and September, up until the first hard frost. Some years there are more than you can deal with. You pick them really until you're almost sick of them. Some years they don't grow at all; those are really bad years.

Mushrooms are either frozen or dried. In the cellar at Lucille's house there is a gas range and, above it, a frame suspended from the ceiling that holds tiers of large screens. Lucille's parents, children, and grandchildren all work together at tables spread with mushrooms, first slicing them and then laying them out on the screens to be hung above the stove. All night long the mushrooms need tending. As those on the bottom screens dry, they are taken off, the top screens are lowered, and new mushrooms are put on the empty screens. Lucille and Sil often sleep in a bed in the cellar while this enterprise is going on. Ten pounds of wet mushrooms make one pound of dry. Some years, after all family members have taken off all the dry mushrooms they want, there will be seventy-five pounds left over to send down to the cousin in New Jersey who sells them in his delicatessen.

The family is together more in the summer. Twenty-two people sit down to Sunday dinner at Lucille's; the tables are laid end to end and chairs are brought from every room in the house. Everyone helps out, but Lucille organizes the dinner. There is more to the task than just minding the food.

In a complex four-generation family, the food is often the least of anyone's worries. There are differences in ages and in-laws, and a raft of children under foot. "There's not much that happens in the family that can be kept private," Lucille says emphatically,

and some people find that tough to live with. We don't; it's second nature. Almost every day, if I don't see her, I talk to

Left: A garden provides fresh food for the family table and for canning or freezing. Below: Early and late summer are times for haying. Before baling became popular, the hay was stacked with a pitchfork.

Nathan Benn, Woodfin Camp

Grandma on the phone. My daughters call me, we check in, we want to know what's going on. If I'm not talking to my older son, I'm on the phone with his wife. Every week or so I call my younger son, who is working out in Idaho, so he'll know what's happening here and we'll know what's happening to him.

When Lucille was a child, her father was a shepherd for a large merino sheep farm. This was before the Depression, while Vermont wool was still able to compete with the large sheep ranches out West. Lucille gestures toward the mountain with the fire tower visible from her kitchen window:

We used to take three thousand sheep in the summertime; we'd drive the sheep through town, drive them to Spruce Mountain and stay all summer. It was all great big open meadows up there. Going, we'd be on the road to Pigeon Pond. It took days to get there. We were kids, and time was forever anyway. It didn't matter to us, we were going for our summer fun. All these things we're doing, we always did together. Dosy, my sister who now lives in Arizona in the winter, is four years older than I am. And Donny, who was killed out West working lumbering when he was only twenty, Donny was just eleven months older than I am. So Donny and I were more together then, 'cause Dosy was always the good one. We were very near Pigeon Pond, that had a beautiful sandy beach. That's where we went swimming; oh it was just a great old time. You know, our relatives used to come up from Massachusetts and spend some time up there. We had a trailer where Ma did the cooking, otherwise we had these tents that we lived in. Got to know a lot of what went on in the world when I was up there.

In those days, forty-five years ago, most of Vermont was open land, only 10 percent tree covered. Now the situation is reversed, and young trees cover the hills and fields. Today cows have replaced sheep, and farming is precarious, with the versatile hill farm still depending on its variety and flexibility to survive the vicissitudes of weather and inflation.

Both in June and in later summer, it was time for gathering in the hay. Lucille recalls that

putting hay up in bales is a comparatively recent thing. We used to put hay into the barn by the forkful, and it packed down ever so tight; the hay didn't breathe then the way bales do now. Come along the end of June, early July, depending on the weather, they would cut the hay and gather it into windrows with the dump

Nathan Bann; Woodfin Camp

rake. The hay had to dry before it went into the barn. We had a horrible fear of fire. The hay was left to get brittle dry in the field before we ever brought it in. If it was wet, it would mildew and ferment. You could smell it. Gases form and it would blow up. The haymows in the barns were divided into sections, so if you smelled the mildew in any one section, you could use that up first.

We would walk down the windrows folding the hay over, making folded piles that could be picked up with the fork and piled up on the hay wagon and later transferred into the barn. Not everyone could pick up these hay piles and load a wagon so no hay spilled between the field and the barn. Marion Martin, who was nearly blind, could make a really good wagonload of hay, doing it by the feel of it. Then each forkload was unloaded one by one and passed up into the barn. They used to have a whole string of people like a chain up in the barn passing the forkload along. Already when I was a child they got big hay tongs, like huge ice tongs, that hung from a trolley way up in the barn. This saved time and a lot of work.

Everyone helped to hay. The old people cooked food in the kitchen, the children lugged water to people in the fields. That hay dust gets in everywhere, in your eyes, down your throat. Good haying weather is hot and the dust sticks and stings everywhere.

Even today you look over next door in the morning and see Tommy's got a lot of hay down and the sky looks threatening, big heavy clouds. All the neighbors come, you get as many wagons as you can. Everybody just goes at it. Before you know it, that hay is in the barn. We all pitched in together on a lot of jobs that were hard, tedious work, making them fun. Like husking corn. Before the corn went into the corn crib to dry, it had to be husked. All the neighbors would come to the barn on a Sunday afternoon, and we would husk and drink and sing. If you got a red ear you could go gather a kiss from the girl or boy of your choice. Sil sings a little song about all this:

The hay's all cut,
the fodder's in the shock,
and the barn's all ready
for the winter stock.

And the thrifty farmer,
says, says he,
time to be a-planning
for a husking bee.

But is there anything that can substitute for standing in the midst of a blackberry or raspberry field, the hot August afternoon ripening the berries almost quicker than you can pick

F. B. Grunzweig

Earlier in this century, most of Vermont was open land. Today, with farming economically precarious, young trees cover the hills and fields, left. A good deer season provides a winter's supply of venison, above.

and eat them, the air rich with their aroma. Or the lush smell of the blackberry pies cooling on the windowsill before supper. Or the taste as you crush a raspberry soaked in new cream against the roof of your mouth.

Every summer it's a question of what to do with more zucchini than anybody wants. The thin little zucchini appear in salads almost before they're big enough to pick. Gradually they turn into tomato and cheese casseroles, are fried with onions, wind up in bread, become pickles, get set in a crock with yeast to become wine. In a good year you can't even give them away. They lie on the vine getting ever larger. When neighbors meet, after taking care of the weather, they complain about zucchini and discuss ways to disguise them.

The first frost of fall always comes before all the tomatoes have ripened. Then a flurry of anxious activity before sunset wraps ghosts of sheets around the tall tomato plants, turning the garden into a silent phantom choir. After the dangerous days at the time of full moon pass, several more weeks of warm weather will turn many tomatoes red, the last crop of parsley and Swiss chard will be cut, all the potatoes brought in.

"Fall is the very best time of the year to make red flannel hash," says Lucille.

You have all those good things right out there in the garden. You put your meat to boiling, corned beef or a ham. You go out to get your beets, carrots, turnips, cabbage, and potatoes and head for the house just as fast as you can. You want to have a lot more beets than you'd dream you ever wanted, to make the hash good and red. First you put the beets in with the meat, the beets are going to take the longest. That's how you guide it. The carrots and turnips get added next. The cabbage and potatoes go in at the end. You cook it until it's just done. You're making a whole lot more of this than you need for dinner. You eat this first with salt, pepper, butter, and vinegar. What's left you grind up in the meat grinder, that makes the hash. Some of this gets put in the freezer so you can pull out a little hash made with all those fresh vegetables all winter long.

You keep pushing right through the summer and fall, right up to deer season. It doesn't ever let up. Everybody's got more jobs to do than hours in the day. Sil always has a real big garden, the whole family is over here so much. You got to take care of it, get it in. Then the old hens come around.

It's not worth carrying most year-old hens over the winter, they can't go outside to forage, feed is expensive, they don't lay. Lucille doesn't keep chickens, but plenty of people do. There's no shortage of old hens for people willing to pick them up live and do them in. Forty old hens on a Sunday morning brings out the whole family. At one end of the line out behind the house, by the big cellar door, Lucille's father is wielding the ax. Sil dunks the dead birds in hot water and hangs them from a beam in the cellar. Many hands pluck out the feathers. Lucille, her mother, and Inda gut and quarter the still-warm birds (Judy hates this job). In front of Lucille is a crockery bowl filling up with yellow unlaid eggs. The packaged hens go into the cellar refrigerator to cool for a day, then into the freezer. All winter long these old hens will be centerpieces for Sunday dinners of risotto and all the fixings. Lucille feels the family learns about their Italian heritage from the Sunday dinners.

Other birds are eaten besides hens. Inda is as good a shot as her brothers at deer, but it's mostly the men who duck hunt from blinds in the bays

of Lake Champlain and who bring in the partridges. Occasionally, other birds—including bluejays, pigeons, crows—are taken illegally. The breasts are baked slowly in a sauce to make *uccellini*, an Italian dish served with polenta. *Uccellini* was prepared more frequently by the preceding generation of Italians—the ones who also ran liquor down over the Canadian border during Prohibition, made wine, and distilled *grappa* (brandy) to sell in their kitchens. But neither the occasional private still nor the clandestine pigeon pie has vanished.

The appearance on porches of stuffed figures with pumpkin heads at Halloween marks the close of the growing year. The side hills have burst into a riot of cinnamon and yellow, brilliant reds, oranges, golds. For a few brief weeks at the end of September and beginning of October, the air, the very wind, is colored by the leaves' display. This is the time for gathering, peeling, and drying apples, for vats of applesauce bubbling on the stove, for apple jelly and apple pie, for Walter Smith's cider, and for don't-drink-it-if-you're-sitting-'cause-you-won't-get-up hard cider.

Already, while the leaves were still in color, there was a little snow. Now as November approaches—and deer season—the wind is sharp, and by Thanksgiving and the end of deer hunting, the ground will have gone white for the next five months. School's been under way again for all the grandchildren for some weeks now, with the stepped-up activity it always requires. The days were far more intense for Lucille and Sil when their children were young.

You got more into it when all the kids were home. Everybody was taking part in whatever we were doing. When we were kids, we almost never went out of the village, the way kids do today. I don't remember going to the city, Montpelier or Barre, ten miles away. We didn't have to go, you just never went. Our fun was wherever we were, we made our own, and we had a great time. If we went to North Montpelier, what we thought were the grown-up people used to come out and play hide-and-seek with us at night. And it was hide-and-seek all over town.

Deer season brings that intensity back again: everyone comes to Lucille's and stays, her children and their families. It's deer camp right at home, with breakfast before dawn and looking all morning for the first deer to be brought in. Then there's deer liver for breakfast the next morning. Each deer is hung out behind the house and in the evening the family takes to the cellar to cut up and package the meat. It's a time for tall tales and for the remembered tales of other deer seasons. For two weeks this goes on, all the adults having saved vacation time for it, kids staying home from school. There are always people having coffee in the kitchen, and Lucille's parents come over for polenta and venison, for mushrooms and deer stew. Some years the family gets enough deer so that everyone gets a good winter's supply. Some years are lean. But whatever deer are taken are shared, starting with Lucille's parents, who no longer get their own.

Lucille tells how one of her sons was so excited the first time he saw a deer that he emptied his whole barrel, six shots, right into a tree, and didn't even know he'd missed.

And once there was an albino deer turned up in the field at the far end of the pond. For a long time nobody shot it, it kept appearing, all white looking, and then you didn't see it any more. But an animal like that could never make it for long. It's a marked thing.

Just as deer season is ending, Thanksgiving comes—a big, festive family time. Everyone is there for the dinner, which includes antipasto, turkey, venison, squash, pickles, cranberries, and gorgonzola and cheddar cheeses. And there is butternut pie, lemon pie, apple pie, and pumpkin pie, all made from scratch. "There are so many of us now," Lucille grins,

that at Thanksgiving we draw names for Christmas. The kids draw kids' names, the old folks do it too. It's a great old time. We've been together a lot, we've been through a lot together, it keeps you together and it keeps you going. Our problem sometimes is we do not know how to make the very best of all the riches we have, it's all so simple.

Winter sets in. Pages get turned down in the well-thumbed catalogs, and orders go off to Sears and L.L. Bean. The whole family goes to Grandma's early Christmas morning for sausages and pancakes and waffles with hot maple syrup, and for the exchange of presents determined by the Thanksgiving drawing. And there is almost always new snow. Years ago the season included sleigh rides and skating on the pond. In those days they cut ice from the pond all winter:

It must be that when they cut the ice, the water would come up over the top and flood it, because 'most all winter it would be just like one huge big skating rink from start to finish. Oh it was fun. People used to come from miles around. All Sunday would be like a big party. We'd have big bonfires right out on the ice and cook hot dogs. We had an old Model T Ford out there that we used to run up and down the pond with, play snap the whip with, we really had an awful good time.

One winter when Lucille was a small child, her father got inflammatory rheumatism and nearly died. "So near that we kids were conditioned for it." She remembers that

he laid in the bed, they had to feed him. They'll never know what old Doc Corson did to pull him through. Finally, when he started getting better so he could feed himself, it got to be Christmas time. Of course, without Dad working for so long, there was no money. So I remember Ma telling us that as we hadn't been able to help with this Christmas, Santa Claus wouldn't be able to bring us anything.

At this time they were having a community Christmas tree down at the town clerk's office. We used to go on the night before Christmas, and there'd be a huge Christmas tree, with a present on it for everybody there, along with the usual candy box full of candy and stuff. Everybody in the town went, there were refreshments, we'd sing Christmas carols. I remember Seth took us down 'cause Ma had to stay home with Dad. Seth was from around here, his whole family was, he was just a little old wizened-up friend, a gentle old guy that whatever he did he had patience with it. He taught you how to do whatever he was doing, explained what he was doing and why, and you didn't soon forget it. Well, Seth took us down to the community Christmas tree, and then brought us home and we all went to bed. But Seth had been a busy person while this was all going on with Dad being sick. When we got up the next morning there was a Christmas tree in the living room with a present for each one us kids under it. And I can see mine to this day—a sled, a sled!

Pretty quickly it gets to be New Year's. People do different things on New Year's Eve, but for many years Lucille and Sil have played pinochle with friends. "That is when you begin to enjoy the winter." Lucille folds her arms and smiles. "It's feeding wood into the stove in the cellar and playing Scrabble at the kitchen table, making a pot of beans, and when the blizzards come, pulling shut the curtains and having some quiet and peace." □

Richard W. Brown

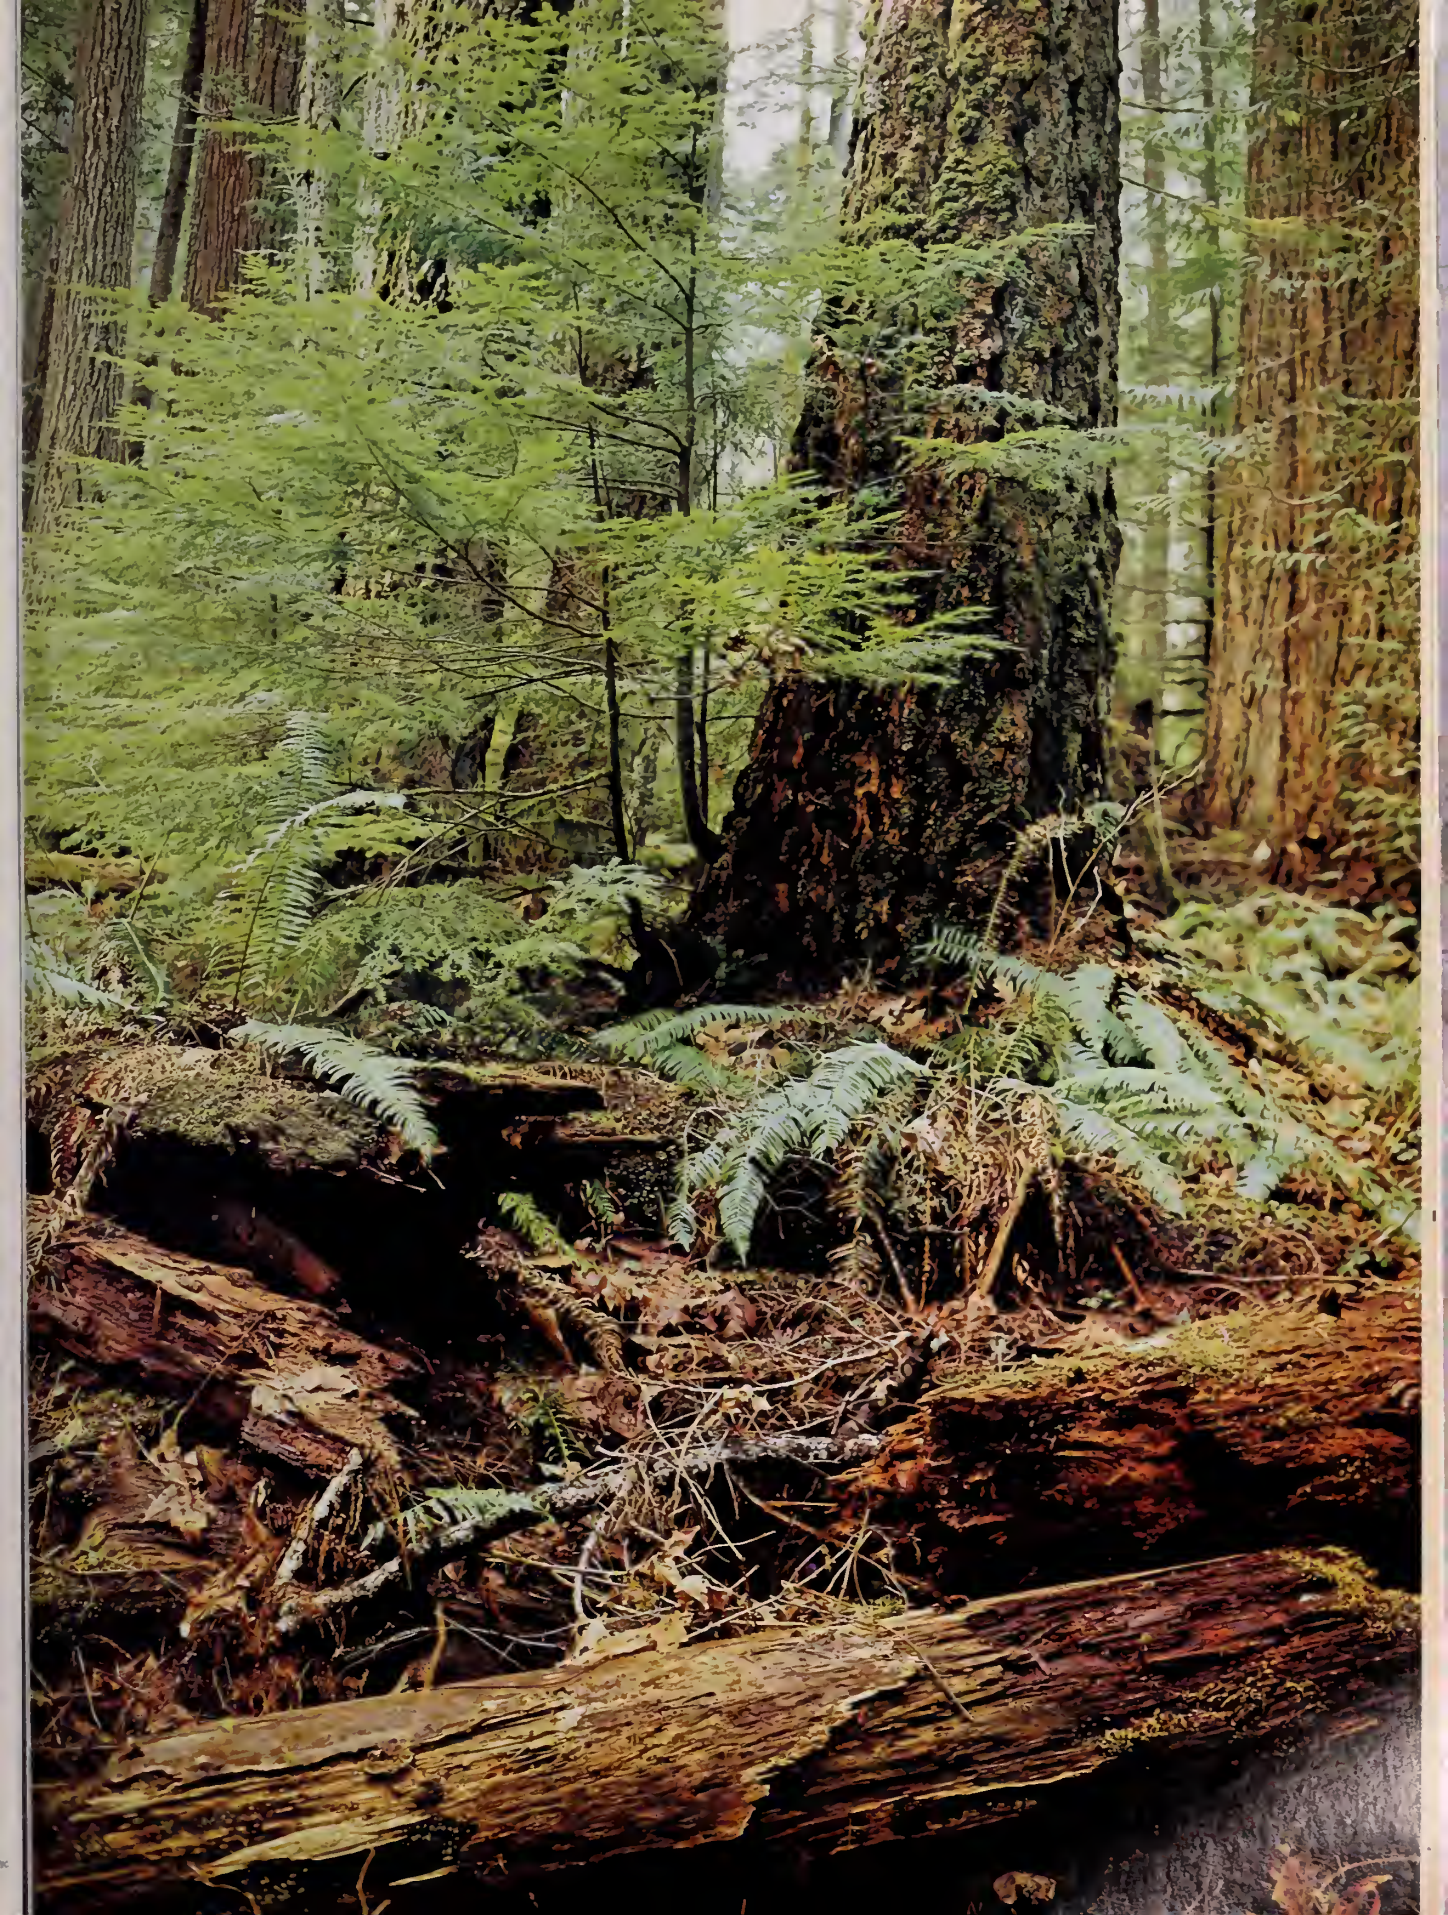
Deadwood Decomposers

On their way to becoming piles of humus, fallen Douglas fir trees support an insect community numbering more than 300 species

by Mark Deyrup

In every forest ecosystem there is an insect community that is instrumental in the death and rapid decomposition of trees. A year after its death, an insect-infested tree in the proper environment has been profoundly changed. The inner bark has been reduced to a conglomeration of insect frass; the outer bark has loosened and is profusely perforated, allowing extensive leaching by rainwater; the sapwood contains numerous insect galleries from which fungal hyphae spread, extracting and concentrating nutrients from the xylem. In succeeding years, as the tree proceeds on its way to becoming an elongate pile of humus, it is host to innumerable insects, which are sustained by the energy and minerals hoarded by the living tree for years before its death.

This community of insects does more than mediate decomposition in dead trees, for some species attack and kill weakened trees in the manner of carnivores removing infirm ungulates from the herd. Insects usually give the *coup de grâce* to suppressed, diseased, or injured trees and branches and to trees in unsuitable sites. Removal of these permanently stressed trees usually promotes the growth and stability of forest stands by reducing competition and recycling nutrients. Insects that attack weakened trees may also attack trees temporarily stressed by drought or defoliation. Removal of these basically healthy trees can drastically alter a forest stand and does not normally contribute to the health or stability of the stand. Overstocked even-aged stands are composed largely of stressed trees that may be readily attacked by insects. If only the weakest trees are attacked, the stand is gradually thinned, freeing the stronger trees from competition. If the entire stand is attacked, it is likely to be replaced by another overstocked even-aged stand that in turn may be devastated by insects.

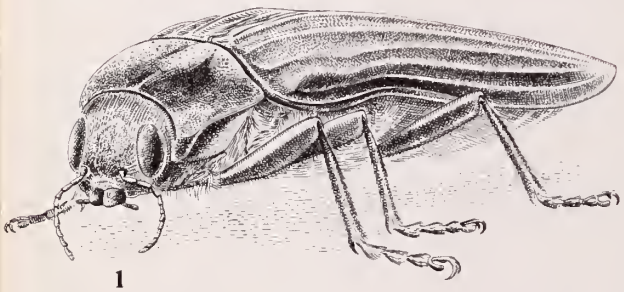


Inspired by the insect community's dual role of architects and janitors of forests, I began a study of dead trees in the Douglas fir forests of western Washington. I started with the idea that the insect community of dead Douglas fir was relatively simple, composed of a couple of dozen species prominent in the literature, but as I read further and dissected more and more dead trees, my list of species grew until it surpassed three hundred. My early elegant diagrams showing the relationships among all the Douglas fir insects grew into monstrous tangles and were eventually discarded. Specimens of insects—identified, unidentified, and unidentifiable—piled up by the thousands. Some of the species had never been described. A simple manual of insects living in dead Douglas fir, a manual I envisioned as a small handbook, swelled to more than six hundred pages. The proposed compact study of a few kinds of bark beetles, a few wood borers, and a termite or two grew into an enormous project easily capable of absorbing a lifetime of research.

The size and complexity of this insect community indicate that insects have found a great many ecological niches in the bark and wood of dead Douglas fir. There are two ways in which insects have carved a multitude of niches in what seems to be a simple resource. First, there is a hierarchy of trophic levels: the phytophagous species, which feed on bark or wood, support parasites, predators, and scavengers. Second, many insects have unique feeding habits due to the nutritional and environmental variables in dead trees.

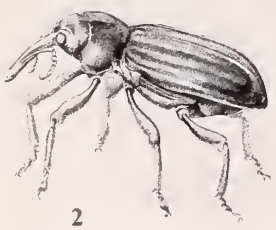
A good example of a phytophagous species with a well-developed group of associated insects is provided by *Scolytus unispinosus*, a small bark beetle that breeds in the inner bark of recently killed Douglas fir, seldom attacking any other species of conifer. This species is restricted to small trees and branches that are partly or completely exposed to sunlight. Its complex life history is similar to that of many other bark beetles. Host trees or branches are located by a female, which begins boring into the bark, usually taking advantage of the shelter provided by bark fissures or twigs. As the female penetrates the succulent inner bark, she apparently releases one or more odor signals (pheromones) highly attractive to both sexes. Soon after beginning her gallery, she is joined by males and numerous females

Each type of deadwood in a stand of Douglas fir—fallen logs, stumps, and branches—supports a vast array of insects. This faunal complexity multiplies because the different insect communities change as the wood decays.



S.J. Krasemann; Peter Arnold, Inc.

The Insect Communities of Dead Douglas Fir



(A Very Incomplete View)

The roots, trunk, branches, twigs, and bark of dead Douglas fir support specialized insects that feed and breed on and in the wood. In the many cases where heartwood or sapwood is preferred, further specialization has taken place. The position of the wood in sunlight or shade is also a determining factor in the composition of the insect community. Each of the insects to which the dead tree plays host is host, in turn, to a variety of predators, parasites, and scavengers.

1

Buprestis aurulenta *(1) is an abundant and conspicuous wood-boring beetle in the Douglas fir forest. Adults feed on conifer needles and mate on injured or recently killed trees. Eggs are laid in bark crevices and in cracks in the sound wood of logs from which the bark is gone. The egg site is usually in partial shade. The larvae feed on sapwood and heartwood and normally require two to four years for development.*

2

3

Pissodes fasciatus *(2) is a weevil that breeds in the fresh inner bark of the trunk. The site has to be shaded and is often on the underside of the trunk. The parasitoid wasp* Allodorus crassipes *(3) attacks the eggs of* Pissodes fasciatus. *Wasp larvae do not kill weevil larvae until the latter are mature.*

Alan Iselin

The bark beetle Pseudohylesinus nebulosus *(4) occurs throughout the geographical range of Douglas fir and is often the most numerous scolytid beetle attacking a stand of these trees. Its abundance is caused by the plentifulness of its hosts—broken tops of live trees, upper trunks of fallen trees, and fallen branches as small as three centimeters in diameter. The species breeds in fresh inner bark that is always shaded, preferring areas that are rapidly losing moisture, through the bark itself or through the transpiration of live needles on adjacent branches.*

Another bark beetle Scolytus unispinosus *(5) has a well-known life cycle. It overwinters as third- and fourth-instar larvae, emerging as an adult between late spring and mid-July. The recently emerged adults feed in the phloem of healthy Douglas fir twigs before beginning their host tree selection flights. They breed in the fresh inner bark of the branches of dead trees that are always exposed to the sun.* Spathius sequoiae *(6) is the largest parasitoid wasp that attacks the larvae of* Scolytus *beetles. Because of the relative shortness of its ovipositor, this wasp can only attack those beetle larvae found near the surface of deadwood. The pinpointing of a host larva might be accomplished through heat perception.* Ecphylus californicus *(7) is a small parasitoid wasp that attacks bark beetle larvae too small to be adequate hosts for other parasitoid wasps. This species is so small, and has such a proportionately short ovipositor, that it can only parasitize host larvae under very thin bark, thinner than is preferred by a bark beetle such as* S. unispinosus.

The longhorn beetle Anoplodera crassipes *(8) often breeds in wood that is old, partly rotten, and at least partly shaded. The beetles remain in the same material for successive generations as the wood decays.*

that begin their own galleries at suitable intervals up and down the tree or branch. The male helps the female excavate a long gallery parallel to the grain of the wood, using a special concave area on the front of his head to scoop out the boring dust. After mating, the male may leave the gallery and go in search of females that have not yet attracted mates. The female remains to lay eggs in small niches along the sides of the gallery. Her supply of forty to one hundred eggs exhausted, the female wedges herself into the gallery entrance where she serves, even after her death, as a barrier to prevent the entrance of young larvae of predators that would eat her young. The beetle larvae feed in galleries extending outward from the egg gallery, each larva doing its best to maintain a thin partition of uneaten bark between itself and its neighbors. In western Washington the larvae overwinter under the bark, pupate in spring, and emerge in early summer in time to start their own galleries in trees and branches downed in winter storms, as well as trees that are showing signs of water stress at the onset of the dry season.

This bark beetle is a common insect and is able to find and colonize almost all suitable Douglas firs. Lifting the bark from a small section of dead Douglas fir, one is almost certain to find a tableau of mother bark beetle guarding the entrance of her gallery and plump white grubs at the end of gradually widening, frass-packed galleries. The tranquillity of this scene is, however, undermined by a series of interlopers. In western Washington I have found twenty-nine insect species in the galleries of *S. unispinosus*. Some of these insects are uncommon in *Scolytus* galleries; these rare insects may be primarily associated with another species of bark beetle or they may be at the edge of their geographical ranges or perhaps their ecological requirements are so restricted that they are seldom abundant. The fourteen species of insects more dependably found in galleries of *S. unispinosus* can be divided into three groups: parasitoids, predators, and associates; the last are composed of scavengers and species whose roles are still unknown.

Parasitoid insects are those whose larvae gradually devour and kill another insect, either working from the inside or the outside. The six common parasitoids of *S. unispinosus* are all tiny wasps, and they all have similar life histories. The female wasp finds a beetle-infested tree, probably locating the site by the odors of resins or alcohol emanating from the galleries of the bark beetles. These species of wasps use their ovipositor to drill through the bark, sting the beetle larva in its gallery, and lay an egg on or near it. The parasitoid wasp larva slowly consumes the host until nothing is left but the hard head capsule and a pellet of crumpled skin. The parasitoid then pupates, transforms to an adult, and gnaws its way out through the bark.

The plumelike tunnels engraved by a brood of Scolytus unispinosus *bark beetles eating their way outward from the vertical egg gallery is a model of efficient use of a rich, but limited, resource. The egg gallery is initiated by the female, which is soon joined by the male. He aids in construction of the gallery by pushing excavated material out the entrance hole. Between 40 and 100 eggs are deposited along the sides of the gallery.*

Alan Iselin

How these parasitoids manage to pinpoint the location of a host larva through the intervening outer bark of the host tree is not known. A much larger species of wasp parasitizing a large bark beetle has been studied by J.V. Richerson and J.H. Borden, and the results of their studies may have some general application. Entomologists originally thought that the female wasp could pick up the vibrations of gnawing larvae, but wasps were shown to be able to locate quiescent larvae. Odor was ruled out by covering a larva with a thin, airtight shield that did

This is for me.

not deter the parasitoid. The investigators finally found a minute difference between the temperature of the bark above the larva and the temperature of the surrounding bark. An artificial warm spot on the underside of a piece of bark elicits initial stages of oviposition behavior by the parasitoid. The sensory receptors involved seem to be a series of microscopic platelets located on the wasp's antennae.

The parasitoids of *S. unispinosus* must know not only the position but also the size of the prospective host larva. A host that is too small produces a miniature parasitoid or none at all. Within the range of host larvae of acceptable size, the smaller hosts still produce parasitoids of subnormal size. Undersized male parasitoids produced from a small host may be at a slight disadvantage when competing for mates and may have a reduced life span due to their small food reserves. Undersized female parasitoids are at a much greater disadvantage because they must use stored food reserves to disperse to a new tree site and produce eggs. Worse yet, the ovipositor length is proportional to the size of the body, so a small female has a short ovipositor that is unable to reach hosts under thicker bark. It would be advantageous for the ovipositing female to lay eggs destined to become males on smaller host larvae and eggs destined to become females on larger host larvae.

My studies of several distantly related parasitoids of bark beetles suggest that the females tend to lay male eggs on small hosts and female eggs on large hosts. The mechanism that determines sex is very simple: all male wasps are haploid, produced from unfertilized eggs, while all female wasps are diploid, produced from fertilized eggs. The mother wasp, like the queen honeybee, controls the sex of her offspring by controlling the release of sperm from a special storage sack that was filled during copulation.

Given the similarities of their life cycles, how can six species of parasitoids coexist on one species of bark beetle? That question cannot be answered completely, but by making notes on the location of parasitoid larvae and then rearing them to adults (the larvae are difficult to identify), I have found several instances of specialization. One parasitoid, *Spathius sequoiae*, and possibly another, *Eurytoma tomici*, usually attack bark beetles living in shaded material. *Cheiropachus brunneri* and *Dinotiscus thomsoni* attack larvae in exposed bark. *Ecphylus californicus* and *Eurytoma phloeotribi* attack young larvae that are too small to be adequate hosts for the other four species. This seems to give *E. californicus* and *E. phloeotribi* a great advantage since they can preempt hosts not yet available to the other parasitoids, but *E. californicus* and *E. phloeotribi* are so small and have such short ovipositors that they can only parasitize hosts under very thin bark, thinner than is actually preferred by *Scolytus unispinosus*.

Predators of *Scolytus unispinosus* are known to include two species of beetles: *Enoclerus lecontei* and *Lasconotus subcostulatus*. Both species are most often found in galleries that the mother bark beetle failed to block with her body. The larva of *E. lecontei* is a large-mandibled, voracious predator that tunnels through the inner bark devouring all bark beetle larvae in its path and probably consuming parasitoid larvae as well. Several *Scolytus* larvae are needed to produce one *Enoclerus*. The larva of *L. subcostulatus* has a different approach, feeding on fungi for its first two larval instars before attacking a *Scolytus* larva. *Lasconotus* behaves almost like a parasitoid, for it slowly consumes a host larva, having first immobilized its prey by stinging it with a pair of caudal organs called urogomphi.

The remaining common associates of *Scolytus unispinosus* include two beetles, four flies, and one wasp. One of the two beetles, *Rhizophagus minutus*, is probably a predator, but it is not known whether this species eats eggs and larvae of *Scolytus* or whether it attacks one of the other associates. The other beetle, *Renardia jubilaea*, and two of the flies, *Sciara* sp. and *Asynapta* sp., feed on a fungus that regularly appears in the galleries of *S. unispinosus*. It is possible that this fungus is a symbiote of the bark beetle, as it has been shown that some other species of *Scolytus* depend on fungi to modify their subcortical environment; these species of *Scolytus*, like many bark beetles, have special cavities, or pits, in which spores of the fungus are carried and nourished with special secretions. One of the fungus-eating flies, an undescribed species of *Asynapta*, is parasitized by an unidentified platygasterid wasp. The remaining species of flies, *Lonchaea corticis* and *Palloptera terminalis*, are primarily scavengers that feed on dead insects such as bark beetle larvae that have died from unfavorable environmental conditions. These flies may actually benefit from the defense of the gallery entrance by the mother bark beetle, for the young maggots often seem to get their start by consuming the internal organs of the dead guardian.

This subcommunity of insects associated with *Scolytus unispinosus* is by no means the most complex of the constellation of subcommunities occurring in dead Douglas fir. *S. unispinosus* has an ecological twin, *Pseudohylesinus nebulosus*, which breeds in the same sort of material but is only found in heavily shaded bark. I have found thirty-three species of insects associated with *P. nebulosus*; most of these do not occur in galleries of *S. unispinosus*. *Dendroctonus pseudotsugae*, the most intensively studied of Douglas fir bark beetles, is known to have forty-three insect associates.

Each of the insects that feeds on bark and wood of Douglas fir has its predators, parasites, and scavengers. The relationship between the associate and its host may be casual, for example, the little *Leptothorax* ants set up their colonies in the abandoned galleries of bark and longhorn beetles. Other relationships are intimate: the wasp *Eubadizon crassigaster* waits with quivering antennae, while the female of the weevil species *Pissodes fasciatus* deposits and carefully covers her eggs in a small excavation in the bark of dead Douglas fir; when the *Pissodes* moves away, the wasp deposits one of her own eggs inside each *Pissodes* egg.

The multiplicity and complexity of relationships between the phytophagous insects and their associates are easily matched by the number and variety of niches that the phytophagous insects use in dead Douglas fir. Specialized habitats have been found by fifty species of bark beetles, twenty-two metallic wood-boring beetles, fifty-two longhorn beetles, six weevils, eight wood wasps, and a dozen or so miscellaneous bark and wood eaters. Careful observation and collecting make it possible to obtain descriptions of the habitats of many species. The longhorn beetle *Phymatodes maculicollis*, for example, usually occurs in recently killed, dry, shaded branches; the false blister beetle *Calopus angustus* may be expected

in soggy, rotting root crowns of small dead trees.

An important factor to dead-tree insects is the portion of the tree available. Root, trunk, branch, twig, bark, sapwood, and heartwood are all grist to the insect mill, but the individual millers are specialists. *Scolytus*, occupying the crown and branches of an exposed dead tree, gives way in the lower bole to the metallic wood borer *Melanophila* and the longhorn beetles *Monochamus* and *Semanotus*, which in turn are replaced in the roots by the bark beetle *Hylastes* and the weevil *Steremnius*. In a cross section of a shaded tree, the bark beetle *Dendroctonus* and the weevil *Pissodes* consume the inner bark, the wood wasp *Urocerus* and the false darkling beetle *Serropalpus* bore in the sapwood, and the longhorns *Opsimus*, *Leptura*, and *Anoplodera* eventually pulverize the heartwood.

Another factor of great importance is the amount of exposure to direct sunlight. A study published by S.A. Graham in 1925 showed that temperatures beneath exposed and shaded pine bark can differ by as much as 35°C. The great temperature extremes in exposed bark combine with accelerated drying and chemical decomposition to make exposed bark and wood a special habitat that must be exploited by specialized insects.

The time elapsed after the death of the tree or branch also determines the composition of its insect community. The bark feeders—rapidly nourished by the abundant and relatively easily digested nutrients of the inner bark—arrive first and leave first. Sapwood feeders begin to arrive at almost the same time as the bark feeders, and in fact many sapwood feeders enrich their diet with inner bark while deeply engraving the surface of the sapwood. Sapwood feeders often require a year or more for development. Insects that feed in rotting sapwood and in heartwood persist for many years, often producing several generations over a period of twenty years or more. Several years after a tree's death there is little left but cellulose and lignin, both materials resistant to digestion. Accumulated resins may make the heartwood still more intractable. Many insects that feed in wood of dead trees are actually unable to digest much wood and derive their nourishment from fungi that permeate the wood.

The fungal flora of the dead tree is one of the most important determinants of the insect fauna, and the insects are often vectors of the fungi. There are many examples of symbiosis, as in the case of the wood wasps, which actually inject fungal spores into the wood along with the egg, or the ambrosia beetles, which cultivate special fungi along the galleries and chambers excavated in the wood. In many other cases insects seem to be associated with wood invaded by certain types of fungi, but the exact relationship between insect and fungus is not known. The fruiting bodies of shelf fungi have distinctive insect faunas separate from the group of insects that feed in wood filled with the hyphae of these fungi.

The insect community of a dead tree is also determined by the season when the tree became available for colonization. When I cut a series of Douglas fir trees at regular intervals, starting in early spring and ending in late fall, I found that trees cut during spring and most of the summer were regularly invaded by the bark beetles *Dendroctonus* and *Pseudohylesinus* and by the weevil *Pissodes*. Trees cut in August and September missed the flight season of these beetles, and by spring the bark had fermented so extensively that it was no longer suitable for insects that feed on fresh bark. These fermenting trees became enormously attractive to the ambrosia beetles *Gnathotrichus* and *Trypodendron*, which are attracted by alcohol. The sapwood of fall-killed trees is quickly riddled with the galleries of three species of ambrosia beetles, which build long, branching galleries lined with a black fungus. The larvae of ambrosia beetles live in small niches, called cradles, and feed on the fungus growing on the walls of the cradle or on a special pellet of fungus supplied by the adults. Wood that has been attacked by ambrosia beetles is filled with pinholes, each surrounded by a black stain associated with the fungal hyphae. Such wood has lost much of its economic value.

Regional factors, too, may determine which insects invade a dead tree. The geographical ranges of many Douglas fir insects are determined by climatic and historical factors, so that insects present in a dead Douglas fir in the mountains of New Mexico are often different from those that are found in western Washington. The insects found in dead trees of one species may be influenced by the regional abundance of hosts of another species. For example, the bark beetle *Orthotomicus caelatus* attacks Douglas fir but is more common in pines; in areas of western Washington where lodgepole pine is abundant, *Orthotomicus* regularly seems to spill over into Douglas fir; but where lodgepole pine is absent, *Orthotomicus* is quite rare. Some insects attack one host in one region and another host in another region: over most of its range the bark beetle *Pityokteines elegans* breeds in pine and true fir, but in northern Idaho *P. elegans* abruptly begins to attack Douglas fir.

All organisms tend toward ecological specialization as they evolve adaptations to enable them to exploit specific resources. This tendency toward specialization is counteracted by the necessity of maintaining a large enough resource base to insure survival. The insect community of dead trees demonstrates the compromises organisms must make between the efficiency of specialization and the benefits of a large, diverse resource base. As described above, there are many environmental and nutritional factors that can be bases of specialization.

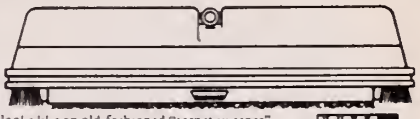
In most forests, however, there is a limited amount of deadwood and bark that becomes available each year through wind breakage, shading out, fire, and attacks by animals and disease.

The usual way dead-tree insects maintain a diverse resource base is by using several species of host trees. Insects that breed in dead Douglas fir usually also use true firs and spruces; many occur in pines, hemlocks, and larches, some in cedars, and a few in broadleaf trees. Similarities in the insect faunas of dead trees can reflect not only morphological and chemical relationships but also the frequency with which different tree species live together in natural mixed stands. Insects with very poor mobility, such as the flightless longhorn beetle *Plectrura*, may be expected to use a great variety of hosts. Species of insects that breed in only one species of tree show not only great mobility but also a tendency to attack very fresh or even living trees. Those insects that attack live trees have enlarged their resource base because they are no longer dependent on external factors such as windstorms to produce a supply of dead material. These observations about the size and configuration of the ecological niches in dead trees are far from complete, but they at least give glimpses of an intricate order that is imposed even upon decomposition.



What can be achieved by a study of the insect fauna of dead trees, what, that is, beyond an odd compulsion to hastily pick apart pieces of wood before putting them on the campfire? One benefit is a more complete, much more balanced view of some insect pests that are normally only studied in the context of economic damage. Then there is considerable satisfaction in adding to our knowledge of insect fauna. It is very easy to obtain original information when looking at a community as poorly known as the insects of dead trees; I have found undescribed species of insects in Douglas fir in city parks in Seattle. Finally, there is a new vision of the deadwood in forest and woodlot, deadwood that is no longer the very symbol of unproductivity, but rather a complex, meticulous recycling station that deposits minerals and humus on the ground, while pouring forth the stored energy of the tree in a swarm of organisms indispensable to forest food chains. □

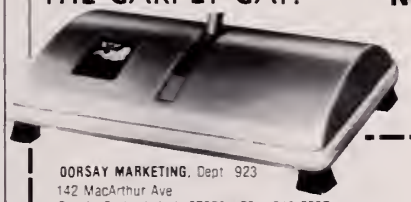
TIRED OF BUYING JUNK?

GET A Carpet Cat®



The CARPET CAT is built with care by people who make nothing else, for people who believe household appliances should last a lifetime. We also think appliances should be noiseless, convenient, pretty, efficient and require no electricity.

If you feel the same way, you're going to love a non-electric CARPET CAT floor and carpet sweeper. We believe it is the lightest, strongest, most efficient and convenient appliance of its type on earth. In the past 6 years, thousands of commercial users worldwide (airlines, hotels, restaurants, etc.) have confirmed our belief by demanding only our floor sweepers. A CARPET CAT weighs under 3 pounds, is only 9 inches wide and works as well on a bare floor as it does on carpet. It picks up sugar, sand, pet hairs, paper clips, ashes and much more. Who really needs a vacuum cleaner?

THE CARPET CAT:

Yes, it looks like an old-fashioned "carpet sweeper" (except it is far smaller and about ⅓ the weight), but there the similarity ends. The CARPET CAT is patented and based on entirely new technology. Its natural hog bristle brush will outlast synthetics by about 3 to 1. It should last a lifetime if properly cared for in ordinary household use. The CARPET CAT'S baked enamel surface wipes clean with a damp cloth. Horse hair corner brushes clean right up to the wall, and the whole sweeper can be hung up in 2 inches of wall space. EVERY PART IS REPLACEABLE AND CARRIED IN STOCK.

If you can find any other sweeper that can make the above claims, BUY IT. We are sure you can't, so we want you to try our CARPET CAT.

Pick up unexpected messes in seconds.

Clean stairs quickly and easily.

Reach hard-to-get-at-places.

NO NOISE, NO HOSE, NO ELECTRIC CORDS

Famous Olde Time 5-Speed

Electric Ceiling Fan

The Charm of a Bygone Era—PLUS Up-to-the-Minute Practicality!

Similar to models selling elsewhere for $199 and more.

Distributes Cool Air in Summer, Warm Air in Winter!

48" Across

ONLY $89.

$10.00 Below Our Own Nationally Advertised Price.

LOWEST PRICE EVER! A nostalgic wooden-paddle fan to grace your casbah. It's quiet-running, energy-efficient, and dramatically decorative. Perfect for home, shop, office.

Ceiling fans have been in use for over a hundred years—And with the energy crunch, they're more practical than ever. In summertime, air conditioners can be set warmer to save electricity, and you'll still get a refreshing cool feeling. In winter, the ceiling fan saves on fuel bills—recirculates warm air downward.

The all-season ceiling fan has metal base, trouble-free motor, weight-balanced, mahogany-finish, wooden blades, stylish brass trim, 5-speed wall-mounted switch. Easy to install; measures 48" across. (UL and CSA listed.)

Z5145540 . . . Ceiling Fan $89.00

OUR GUARANTEE: You must be absolutely delighted. If not, simply return within 30 days for a prompt full refund of purchase price . . . No questions asked! We ship within 48 hours; delays notified promptly. Delivery guaranteed within 60 days.

A Sad Reflection of the Outside World

by Ian Tattersall

A World Like Our Own: Man and Nature in Madagascar, by Alison Jolly. *Yale University Press, $29.95; 272 pp., illus.*

Madagascar, as the title of Alison Jolly's new book elegantly hints, is another world; if any place deserves the much abused title of "unique," this is it. The thousand-mile-long microcontinent possesses almost every type of biological community found elsewhere in the tropical world. But on Madagascar, which has been separated from its parent continent, Africa, for upward of a hundred million years, each community is strikingly different. Rates of endemism—of uniqueness of species—are extraordinarily high, and in the aggregate, this translates into a remarkable singularity of gestalt.

Way back, the great island formed part of ancient Gondwanaland, the vast landmass that broke up to give us the southern continents we know today. At that time Madagascar shared the same pantropical flora and fauna with its neighboring regions. But since the breakup, which took place before the great periods of diversification of many important biological groups, including the flowering plants and the mammals, the flora and fauna of Madagascar have been free to evolve in relative isolation from the outside world. I say "relative" isolation because not all the plants and animals in Madagascar today are descended from those living on the island at its separation from Africa. Immigrants have crossed the water barrier from time to time, although most of these apparently did so at an early stage; recent arrivals such as the now extinct pygmy hippo seem to be the exception rather than the rule.

The upshot of this history of isolation and highly selective invasion is an extraordinary natural experiment that tells us, in Jolly's words, "which rules would still hold true if time had once broken its banks and flowed to the present down a different channel." The founding species of the modern Malagasy biota were presented with virtually all of the ecological opportunities available at similar latitudes elsewhere, and the descendants of this restricted spectrum of species have radiated to fill this vast ecological space. There are relatively few major animal groups living in Madagascar, but most of those present are represented in great adaptive variety, producing, from different roots, entire ecological communities that parallel those existing outside. Take, for example, the lemurs, the subjects of Jolly's own specialized studies in Madagascar. These primates, members of a suborder represented elsewhere only by a handful of small, nocturnal genera, display in Madagascar a full and fascinating adaptive spectrum within which remarkable parallels to other animals are found. For instance, not only did the lemurs evolve baboonlike diurnal ground-living quadrupeds and a large, orangutanlike arboreal hanger, but they also produced their own ecological equivalent of the woodpecker, the Malagasy aye-aye.

Sadly, however, Madagascar reflects the outside world in another way, too, and this is what *A World Like Our Own* is essentially about. Although it was the last major inhabitable landmass to have been invaded by humans, Madagascar is already one of the most devastated. Less than two thousand years ago, teeming forests covered virtually the entire face of the island. Now, thanks to the twin assaults of ax and fire, the forest protects a mere few percent of the land area, and the island's lifeblood, its soil, bleeds steadily away to the sea. Already entire vegetal formations have disappeared; many of the most fascinating animal species of Madagascar are gone forever. The pseudobaboon and the pseudoorangutan, for example, are known today only from their subfossil bones; the "woodpecker" hangs on by the merest of threads. It is easy to separate those species still living and those now extinct into separate compartments of the mind. But in Madagascar the division is an unreal one; both the living and the extinct are participants in the same process: human destruction of nature. And it is with this process that Alison Jolly is above all concerned. Individual species, even those most lovingly described, appear almost as incidental characters in her book; the conflict between man and nature is the predominant theme.

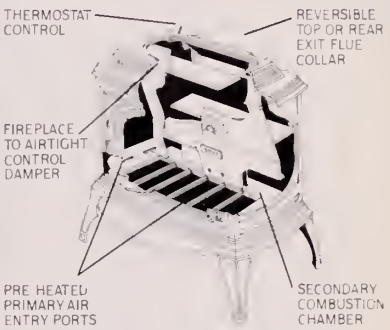
Jolly recounts the story of a five months' journey through Madagascar. She has done almost everything, been almost everywhere. She has climbed mountainsides through dripping rain forests in the company of cut-and-burn farmers and has contemplated ruffed lemurs bouncing through the treetops; she has held earnest conversations

FROM THE STATE OF VERMONT... COMES THE STATE OF THE ART

The VIGILANT, our middle-size stove. Shown here as a free-standing unit, it may also be enjoyed in a fireplace installation, providing a friendly fire of crackling logs with doors open — a superior heating unit with doors closed.

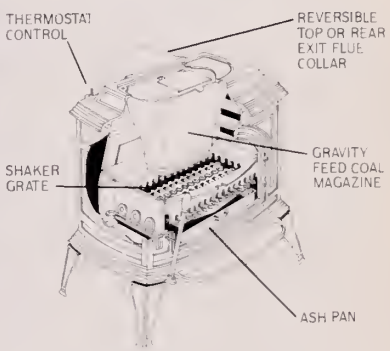
Vermont Castings Defiant, Vigilant and Resolute are truly American Classics. From the original Defiant, our largest model, to the Vigilant and Resolute, every stove is built with the conviction that beauty and efficiency can be combined without compromise. Crafted by hand in solid **cast iron,** these superb **airtight** stoves offer you a lifetime of dependable, economical heat. The unique and graceful curve of the stove front, with its classically arched doors, is your symbol of original Vermont Castings design.

A significant new breakthrough in wood to coal convertibility. The Vermont Castings Vigilant and Resolute are designed to burn either wood or coal with equally high efficiency. Our advanced thermal engineering and unique "stove within a stove" design make it possible.



There's no fear of making a costly mistake in your choice of fuels — now, or later. Our optional coal conversion unit gives you the flexibility of using either wood or coal, whichever provides the greatest economy and meets your personal needs. Best of all, you can add the conversion unit at any time.

Each model offers every feature knowledgeable stove enthusiasts demand. Vermont Castings stoves make use of sophisticated baffling systems to provide extremely long flamepaths, minimizing flue heat loss. Pre-heated air passages and true secondary combustion chambers maximize heat and fuel economy.



Automatic thermostat control allows you to pre-set your stove at the desired level of heat output to burn slowly and evenly all night long on a single smokeless loading.

Before you buy any stove, mail coupon today for our complete ENERGY-SAVER INFORMATION KIT. Compare . . . then decide.

Classic Beauty and Advanced Thermal Engineering Combined in America's Finest Cast Iron Stoves

Russ Kinne; Photo Researchers

Small ears and a pointed, foxlike muzzle are characteristic of the sifaka, one of the many lemurs found in Madagascar.

with central government officials in the capital and has commiserated with beleaguered foresters in the field; she has talked with a king on his off-hour from operating the police station switchboard and has picked wickedly barbed thorns from her skin in the spiny, arid forests of the south. All of this, and much more, she reports in a marvelously evocative way. If you never visit Madagascar yourself, or perhaps even if you do, you are unlikely ever to know it better than you will through the pages of this book. For those who like their images visual, there are a hundred black-and-white photographs by Russ Kinne. They provide an excellent complement to the text, but one still regrets the dearth of color photographs. By their isolation, the six that have found their way into the book simply emphasize the lack of others.

But *A World Like Our Own* is, as I have suggested, much more than mere travelogue. It tells two parallel stories: that of the decimation by humans of the Malagasy flora and fauna and that of the Malagasy peasant's struggle for survival. Both stories are moving, and both are movingly told. Jolly sees the destruction of Madagascar's treasurehouse of plants and animals and is deeply concerned. But she also sees the plight of the peasant who must feed and shelter his family, and who cannot afford to think of tomorrow when today's needs are so pressing. And she sees beyond both of these things: that while for the moment further forest destruction will keep the peasant and his family alive, ultimately there will be no more forest to destroy, and the peasant will have to find some method other than cutting-and-burning to earn his livelihood or starve. But what? For with the disappearance of the forest come the disappearance of nutrients from the soil, the disappearance of the soil from the slopes, and the disappearance of the water from the streams. This is no mere doomsday extrapolation to something that may happen if present trends continue unchecked—it has already happened over much of the island. Not for nothing has Madagascar been described as an island the "shape, color and consistency of a brick." I remember my own reactions upon flying over Madagascar for the first time: the landscape below looked brown, dead, forlorn. How, I wondered, could this possibly be the home of the most fascinating forest fauna on earth? Cut, burn, plant, harvest, and move: this has been the human pattern on Madagascar for centuries. But in the past there was much more forest; in the past the island was not home to nine million people, half of them under twenty.

All of this Alison Jolly sees, describes, understands. But if there is one flaw in this charming, tolerant book, it is that it is too charming, too tolerant. Jolly's sympathy is almost too complete. It is somewhat as if she were describing a Garden of Eden in which eating the apple had itself become a sacramental act. She was sent to Madagascar by the World Wildlife Fund, an organization presumably devoted to saving other species from extinction rather than to preserving the life style of peasants.

Yet there is nothing in the book of the sense of helpless outrage that so often engulfs one in Madagascar, and something akin to that has to lie at the heart of the activities of conservationists everywhere. Of course, such emotion has to be balanced by pragmatism, by a sense of reality; but if it is overbalanced, we are paralyzed. There are places in the eastern humid forests of Madagascar where one can stand on a mountain crest and see the rain forest stretching away, ridge and valley, for as far as the eye can discern. Its very immensity creates an almost tangible presence, a sense of permanence, of inviolability, as if this were how the world had from the beginning been meant to be. Then, by turning one's head no more than ninety degrees, one sees devastation: clearings, vast and small; spirals of smoke rising lazily into the air, signaling the imminence of the end of what still remains. And one doesn't want to understand. One doesn't sympathize.

For if one did, if one really understood the human needs that underlie such devastation, could one really seek to stop it? The destruction is not wanton; its causes lie far beyond what could be achieved by a few conservation-oriented grants, while a Third World government beset by the immediate problems of feeding an ever expanding population can hardly afford to take a long-term view. Successful conservation under these conditions requires a certain degree of monomania, a refusal to acknowledge the full, daunting dimensions of the problem. Alison Jolly's book is less than satisfactory as a conservationist tract precisely because it reminds us so clearly of the difficulties involved, the more powerfully since it presents them at an intimately human level. And as its title reminds us, the problems are not Madagascar's alone. The island is indeed a microcosm, and both despite and because of its shortcomings as a tract, this sensitive book should be read by all who are concerned about conservation worldwide. And by others, too, for it is the finest modern evocation in our language of the unique, fascinating, and unfamiliar world of Madagascar.

Ian Tattersall is associate curator in the Department of Anthropology at the American Museum. He has traveled and worked extensively in Madagascar, where he has studied various aspects of the biology of lemurs.

Fine art. Fine value.

"Femme Bleue," an original lithograph by Linda Le Kinff, typifies the very remarkable value that Christie's Print Collection offers in original etchings and lithographs. Attractive landscapes and figurative works by rising young artists from $100 to $150. As well as the work of such masters as Chagall, Moore and Miro.

Each work is an original, numbered and signed by the artist. Then it is stamped with Christie's seal of authentication and delivered to your home.

Let us send you our free colour portfolio and price list. There's no better place to buy original prints. No better time than now.

RATES AND STYLE INFORMATION

$1.75 per word; 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine. Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired. Occasionally, slight editing is required for clarity. Thank you!

A Near Miss

Almost a decade ago, a large meteoroid came within thirty-six miles of the earth. The same meteoroid is expected back in 1997, when if all goes well, it will come no closer

by Stephen P. Maran

A brilliant object, apparently trailing smoke, streaked northward across the sunny sky in August 1972, shattering the lazy summer afternoon from Utah north to Alberta, Canada. In some places, startled observers also heard sonic booms and called the police to report an aircraft in distress. Among the observers, however, were several amateur astronomers and, by rare luck, a vacationing expert on meteor physics. These spectators immediately realized that they were witnessing one of the rarest of meteoric phenomena—a daylight fireball.

Only later, when many firsthand accounts were compared, did the expert, Luigi G. Jacchia of the Center for Astrophysics in Cambridge, Massachusetts, realize that he had seen an event unique in recorded history: the earth had been "buzzed" by a large meteoroid that neither crashed to the ground nor broke up in the atmosphere, but actually escaped back into space. Recent calculations show that the August 10, 1972, meteoroid is coming back and that it will pass the earth again in 1997, with only a slight chance of hitting our planet the second time around.

Meteoroids are chunks of rock and iron that move through space in orbits around the sun. If they reach the earth's surface, they are termed meteorites. The flash of light produced as a meteoroid streaks through the lower atmosphere is known as a me-

teor, and an exceptionally brilliant meteor, corresponding to a large meteoroid, is called a fireball. These terms are loosely used; a scientist will often write "meteor" or "meteorite" when "meteoroid" is actually meant.

The event in August 1972 was unquestionably a fireball, since even in broad daylight it was a spectacular sight. It also qualified as a bolide, or a fireball accompanied by sonic booms.

When a meteoroid encounters the lower layers of the earth's atmosphere, it is slowed by air resistance, while friction heats it, melting away some surface material. In the process, most meteoroids are reduced to dust or to small fragments. Among the uncounted millions of meteoroids out in space, there must be many that have grazed the uppermost layers of the atmosphere and then continued on their journeys. Nothing is known of such encounters, however, since they are not detectable from the ground.

Meteoroids are just small asteroids, and indeed the practical distinction is that asteroids can be viewed through telescopes, while meteoroids are too small to be seen except when they flash through the lower atmosphere. As a result, astronomers keep track of a few thousand asteroids, but have no specific knowledge of any of the immense number of meteoroids that exist in the solar system. (The streams of comet dust that produce "meteor

Celestron®

For the photographer, astronomer, naturalist, educator, or casual observer — Celestron has established a new standard in superb telescopes and telephoto lenses at affordable prices (from $295). All feature large observatory mirror/lens type optics folded into a compact, lightweight, portable telescope or telephoto lens. Close-up detail borders on the fabulous from celestial objects light years away, to ships, planes, flowers, wildlife or people. Here is truly an instrument that allows you to observe or photograph the world around you. Celestron also has a full line of binoculars of astronomical quality.

Send $2.00 for 32-page full color catalog on how to select and use a Celestron telescope or telephoto lens.

showers" on schedule every year are a wholly different phenomenon.) The single exception is the August 10, 1972, meteoroid, the only one whose future whereabouts can be calculated.

The reports of sonic booms are what suggested to Jacchia that the meteoroid had continued on into space. Near the middle of the observed flight path, Montana viewers heard the sonic boom, although those who saw the fireball farther to the north over Canada heard nothing. If the meteoroid had continued to fall to lower altitudes, it would have "lowered the boom," producing louder sounds than those heard in Montana. But a sonic boom generated at heights above thirty-seven miles will reflect upward from the atmosphere below the generating source, thereby preventing any sound from being detected at ground level. For this reason, Jacchia concluded that the meteoroid must have been lower than thirty-seven miles while over Montana, but higher than that over Alberta, where it must have been on the way up, not down. This interpretation was confirmed when precise measurements of the meteoroid's altitude became available from an unexpected source, making it possible to determine the orbit of the space visitor.

The unexpected source of fireball-tracking data was an artificial satellite orbiting the earth, which actually viewed the fireball from above. Details of the satellite findings were disclosed in 1974 by a group of physicists from the Aerospace Corporation and the Aerojet ElectroSystems Corporation, two military-contractor organizations in southern California. According to their report in the February 15, 1974, issue of the periodical *Nature*, infrared radiation was recorded by the satellite when "the meteor first became sufficiently hot to be detected over Utah," and the measurements continued for about 100 seconds until the fireball "finally cooled below the detection threshold," 930 miles to the north. During this time, the meteoroid traveled along a shallow, curved trajectory at speeds in excess of 31,000 miles per hour. By the physicists' reckoning, it carried an energy of "approximately the yield of the nuclear weapons [that] destroyed Hiroshima and Nagasaki." Analysis of the satellite measurements also showed that the low point in the meteoroid's flight was 35.9 miles above the ground in east-central Idaho, a few miles south of the Montana border, confirming Jacchia's deduction.

The meteoroid energy referred to above is not the chemical or nuclear energy of a bomb but rather what is called the kinetic energy of a rapidly moving, massive object. When this kinetic energy is released by the object on impact, however, it can have an explosive effect. The best illustration of this phenomenon is Meteor Crater (which should, of course, be called Meteorite Crater), a ¾-mile-wide scar in the northern Arizona plateau. Meteor Crater is at least 30,000 years old, and most of the large impact craters on the earth are even older, indicating that major meteoroid impacts are now very rare.

There has been much controversy over the size and mass of the August 1972 meteoroid. One estimate is that it was a stone of about a million tons, with a diameter of 260 feet. At the other extreme is a calculation suggesting that the object may actually have been smaller than the stone meteorite that fell harmlessly in pieces near Jiling (Kirin) in the People's Republic of China in March 1976. The largest fragment of the Jiling meteorite weighs 3,900 pounds.

The disagreement over the August 1972 meteoroid has several roots: misprints in tracking data, which may have affected some scientists' calculations; differences in computing methods; and uncertainties about the brightness of the fireball and the composition of the meteoroid. *Nature* gave the results of the satellite measurements, in terms of the speed and altitude of the meteoroid, for only three locations along the fireball path, but it turns out that the longitude of one location and the latitude of two were listed incorrectly.

The methods that various researchers used to compute the meteoroid's mass involved deductions from its infrared radiation, from its apparent brightness, and from the rate at which the flying object was decelerated by air resistance. The conclusions reached about the mass and the size of the meteoroid, regardless of the computation methods, depend on whether the meteoroid was made of stone, of iron with a high nickel content, or of a combination of stone and iron. These substances have very different densities. The actual density of the August 1972 meteoroid will affect the results of the computations made by any method, but no one

knows the composition of that meteoroid.

The problem posed by deriving the meteoroid's dimensions from satellite measurements of the intensity of infrared radiation was the lack of precedent. Since the technique has never been applied before, no one knows how reliable it is. Deductions made from the brightness of visible light, on the other hand, are based on the "luminous efficiency" method, which, although it has often been applied, is nevertheless suspect. In this method, the mass of the meteoroid is computed from a relation between meteoroid mass and observed meteor brightness. In some cases, this relationship has been determined by studying the brightness of artificial meteoroids fired from rockets. The parameters that relate brightness and mass depend on what a meteoroid is made of, and they have been determined from rather small meteoroids. We do not know whether the derived relationships can be extrapolated to objects as large as the 1972 meteoroid.

Another difficulty is that although the August 1972 fireball was seen by thousands of people, its visible-light brightness is not accurately known. There was nothing suitable in the sky to use as a standard of comparison. Witnesses agreed that the fireball was much brighter than a full moon but far dimmer than the sun. This still leaves considerable margin for error.

The technique of estimating meteoroid mass from the rate at which air resistance slows a flying object is sensitive to the composition of the meteoroid, but as mentioned above, the composition of the August 1972 meteoroid is simply not known. Most astronomers have assumed—or guessed—that this meteoroid was a stone, since the great majority of meteoroids are thought to be stones. Laboratory measurements of meteorites, however, show that even the stone ones vary widely in density. Uncertainty over the actual density will affect the mass deduced from an observed deceleration since if two objects of the same mass travel the same path at the same speed, the less dense object, being larger, will suffer more resistance by the air. Another, less serious problem is that the mass of the August 1972 meteoroid was not constant from one observation to the next. As shown by the eyewitness reports of smoke behind the fireball, it was losing mass along its trajectory. The smoke, a phe-

For centuries man feared it, made sacrifices to it, wailed over it. Now we run to greet it. You are extended a unique invitation to witness one of nature's most awesome spectacles, a total eclipse of the sun. On July 31, 1981 the British cruise ship, m.s. Coral Princess will be positioned 1000 miles off the coast of Japan to rendezvous with eclipse totality.

The ORIENT ECLIPSE CRUISE and expedition is the sequel to the six previous historic VOYAGE TO DARKNESS eclipse expeditions which successfully intercepted totality off the coasts of Nova Scotia, Africa, the Caribbean, in the Pacific and at Montana's Big Sky eclipse expedition.

The ORIENT ECLIPSE CRUISE adventure offers a distinguished staff of shipboard lecturers (including meteorologist Dr. Edward M. Brooks) scientific, cultural and educational programs, and tours of Japan, Hong Kong, Macau and China.

Join us as we probe earth, sea and space for yet another exciting and memorable cosmic adventure as we sail into totality and beyond.

Mid-Winter Savings Now In Effect!

At last—an efficient woodstove beautiful enough for your home

The WESO Ceramic Tile Stove enhances the beauty of the most tastefully decorated home, where a black metal heater would be rudely out of place.

You can see the flames flickering behind the wrought-iron style grille as the WESO — which employs both convection and radiant heat — surrounds you with gentle all-over warmth.

The WESO burns both wood and coal, holds a fire all night without tending, and offers every efficiency feature you could ask for. Now available in your choice of seven decorator tile colors.

Enclosed is $1. Rush me your literature showing the WESO CERAMIC TILE STOVE in all 7 tile colors — plus details about WESO's new COALBURNING STOVE — and shipping schedule for winter delivery.

nomenon that astronomers call a meteor train, consisted of material shed as the meteoroid was heated by friction with the air. In addition, the mathematics of the deceleration method were established for typical meteoroids, which fall along fairly steep paths, rather than for an object such as the August 1972 meteoroid, with a grazing trajectory like that of a stone thrown to skip off water.

In view of the foregoing, it is hardly surprising that published estimates of the mass of the August 1972 meteoroid have ranged all the way from two tons to one million tons. Recently, however, a new analysis has given us what is probably the most reliable available information.

The new study is by Zdenek Ceplecha, an authority on meteor observations at the Astronomical Institute of the Czechoslovakian Academy of Sciences. He analyzed the full list of satellite measurements, which has never been published, and developed an improved deceleration method that allows for both the grazing trajectory and the frictional shedding of matter by the August 1972 meteoroid. By internal cross-checking, Ceplecha determined that the errors that affected the original list of measurements in *Nature* had been eliminated. There is still no way to get around the unknown density of the meteoroid, even by means of the improved deceleration method, but it seems likely that the meteoroid is a stone of 100 to 1,000 tons, with a diameter of twelve to thirty feet.

The most interesting aspect of Ceplecha's work, for me, is his calculation of the future orbit of the August 1972 meteoroid. The object no longer follows its original path, having been disturbed by its 1972 encounter with the earth. Instead, it now revolves around the sun approximately once every 21½ months, following an elongated elliptical orbit that brings it out into the asteroid belt, far beyond Mars, and then back toward the sun, reaching almost six million miles inside the earth's orbit. The orbits of the meteoroid and the earth cross at one point in space, but thankfully both objects do not usually pass this place at the same time. They won't even come close until August 1997, when the meteoroid will have completed fourteen orbital revolutions since it zoomed past Idaho at an altitude of less than thirty-six miles in 1972.

In 1997, the meteoroid is expected

to zip by the orbital intersection point four days before the earth gets there, so all should be well. The only hang-up is that, according to Ceplecha's calculations, this conclusion has an eight-day uncertainty factor. Thus, the meteoroid may pass the intersection point as much as twelve days before or four days after the earth gets there. This means that a slight but real possibility exists that both orbiting bodies will reach the intersection at the same time. Should that happen, no one would choose to be close to the place on the earth where the meteoroid would hit, but there is no way to judge where that place might be. Perhaps by 1997 we will have the technology to detect a large incoming meteoroid before it strikes the earth's atmosphere and to determine the danger zone. In the meantime, lacking any such ability, let's hope that we have no worse natural disaster to fear between now and the likely miss in 1997.

Picasso

Imagine the beauty and excitement of these sculptures in your home...

Shown much smaller than actual size—Each 12" High.

"L'HOMME ET LA FEMME" BY PICASSO
22 KARAT GOLD LEAF/EDITION LIMIT: 750

Picasso's towering genius blazed a trail of glory across the arts of the twentieth century. His immortal works of art are a joy and delight to own and to live with.

Now, Collectors' Guild, Ltd.—one of America's oldest, largest and most distinguished societies of collectors of original works of art—is privileged to present an extraordinary limited edition of Picasso sculpture: "L'Homme et la Femme."

Each is hand-leafed in 22 karat gold over foundry stone® by APF Studios, who have served such leading museums as The Metropolitan Museum of Art and the Smithsonian.

The 22 karat gold leaf is meticulously applied by skilled craftsmen by hand to achieve a brilliant, flawless gold surface. Mounted on polished marble, the sculptures are works of dazzling beauty and perfection...to enjoy now and to pass on with pride to future generations.

These superb works of art are available exclusively from Collectors' Guild in a serially numbered edition permanently limited to 750. A Certificate of Authenticity will accompany your sculptures.

Orders will be filled in strict sequence of receipt so it is important to act promptly.

Celestial Events

by Thomas D. Nicholson

The Moon The waning crescent moon will be in the east to greet early risers on the first few days of March. The moon will then disappear as it passes between the earth and sun and becomes new on the 6th. The evening crescent should show up in the western sky at dusk on about the 9th, waxing to first-quarter on the 12th. From then until full moon on the 20th, expect bright moonlight during early evening hours and throughout all or most of the night. Last-quarter is on March 28, the next new moon on April 4, and first-quarter on April 11. Perigee moon (nearest the earth) is on March 8 and April 5; apogee (farthest from the earth) on March 24.

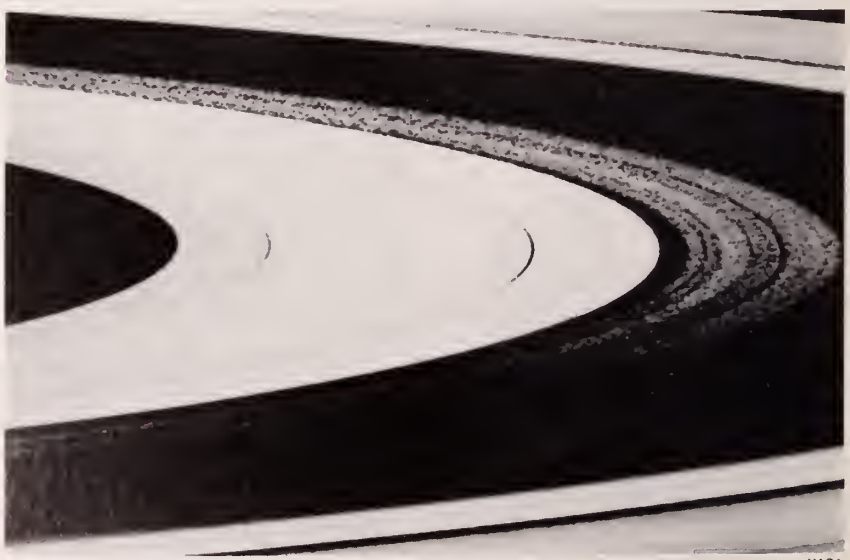
Stars and Planets We haven't seen bright planets in the evening sky since summer, but now, at long last, Jupiter and Saturn are back in and Virgo is to the right of its bright star, Spica. They are quite close to one another, rising in the east after dark and high in the south about midnight. Jupiter is easily the brighter of the two, the brightest starlike object you will see at night this month. Saturn, a little to its left and above it, is less than one-fifth Jupiter's brightness, about as bright as Spica. Both planets are shifting west through the stars, as you can see by watching them drift slowly away from Spica. But they will remain close to one another through this coming summer. Jupiter and Saturn are also prominent in the morning sky, where they set in the west at about dawn. All the planets are morning stars until late in March except Mars, which becomes one in early April, when Jupiter and Saturn are technically evening stars. None of the other planets are located where they can be seen.

The sun, in March, moves easterly through the stars of Aquarius until the 13th; it then enters Pisces. Mercury moves from Capricornus to Aquarius, Venus from Aquarius to Pisces, and Mars from Aquarius also to Pisces, but with a brief skip through a corner of Cetus. Jupiter, Saturn, and Pluto are in Virgo, Uranus in Libra, and Neptune in Ophiucus.

March 1: Mercury is stationary among the stars and resumes its direct (easterly) motion as a morning star.

March 11–12: The bright star near the moon tonight is Aldebaran, in Taurus. The moon passes very close above Aldebaran at about 12:00 A.M., EST, on the 12th, so close that it covers the star (an occultation) over northern Canada and Alaska.

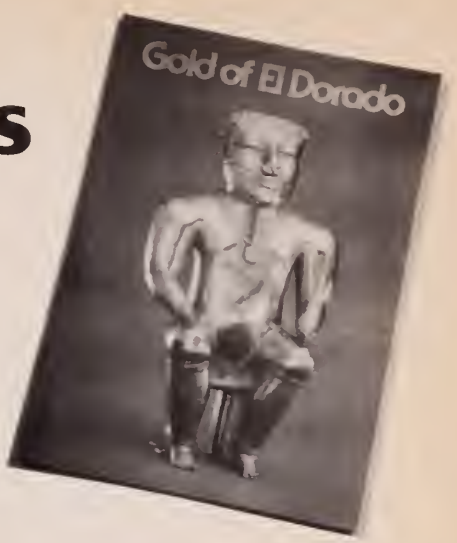
March 15: Mercury is at its greatest westerly elongation (greatest distance to the right of the sun). That would ordinarily be an excellent position for a morning star. But this is not a good elongation; the planet rises too late and too slowly to be seen in the morning twilight.



March 20: The sun arrives at the vernal equinox at 12:03 P.M., EST, and spring begins in the Northern Hemisphere (autumn south of the Equator). Although today is the official date of the "equinox" (meaning night and day are of equal length), the length of the day (the interval from sunrise to sunset) has been more than twelve hours since the 17th. The full moon is near Jupiter and Saturn tonight. Watch it drift slowly above the two planets, passing closest to Jupiter at about 8:00 P.M., EST, and to Saturn about three hours later.

March 26: Jupiter and Saturn are at opposition, located opposite the sun in our sky. They now move into the evening sky, rising before sunset, setting before sunrise.

April 2: Mars is in conjunction with the sun, ending its long sojourn as an evening star. Although it now becomes a morning object, it will not be worth looking for until next December.



April 4–5: New moon is on the 4th, perigee about twenty-four hours later. The effect of perigee will enhance the usually strong spring tides. Expect exceptionally high tides the night of April 5.

April 7: Venus is in superior conjunction, in line with the sun and earth but beyond the sun. The planet now leaves the morning sky and becomes an evening star, but not a very prominent one until June.

The rings of Saturn NASA

An Art Book That Took Centuries To Create

It took the American Museum of Natural History four years to arrange its exceptional exhibition of more than 500 pieces of ancient gold from Colombia. But those few years are a brief time when compared with the decades archeologists have spent digging (literally!) and studying the gold artifacts from tombs, caves, and buried sites. And all that time is short when compared with the many centuries prehistoric Indians practiced their craftsmanship and artistry to create these treasures.

So when it became the United States sponsor for this outstanding collection, the American Museum faced a dilemma. Could we do justice to all this effort and scholarship and beauty? We think we have. First, by dramatically displaying *Gold of El Dorado: The Heritage of Colombia* in one of our largest halls. The glowing reports from visitors tell us our efforts have been worthwhile. If you don't have a chance to see the show for yourself in New York, we hope you will see it in Chicago, San Francisco, or New Orleans on its year and a half tour.

The second challenge for the American Museum was the creation of an appropriate book to accompany the exhibition. We decided against a traditional catalog; against a small, boring volume with tiny black-and-white pictures that could never do justice to these fine objects. Instead, we decided to present a select number of the finest pieces of pre-Columbian gold in a large, stunning format. And to represent the three important elements that make a great art book we chose outstanding professionals.

First, photographer Lee Boltin. One of the greatest photographers of art objects, he also took the famous pictures of the Tutankhamun show. We sent him abroad to find and record great pieces of pre-Columbian art.

Second, archeologist Warwick Bray, from the University of London. One of the world's foremost authorities on pre-Columbian art, Bray is also a skilled writer, able to present fascinating background in a succinct, readable essay in the book. Dr. Bray organized the Colombian gold exhibition in London.

Third, Harry N. Abrams, Inc., America's leading publisher of fine art books. In a co-publishing venture with the American Museum, Abrams designed the book, supervised the preparation of 30 large color plates, and monitored the fine-quality printing.

The result is an unprecedented exhibition book. It is bold and big—each plate is 16 by 11½ inches—bigger than this magazine *opened up*. The paper is heavier than most posters. In fact, many persons have purchased two copies of the book in order to have one set of these fine art prints for framing.

And now for the happy ending. Because the Museum is a co-publisher, we are able to offer this soft-bound art book at a major savings from its normal retail price of $12.50. We are pleased to offer *Gold of El Dorado* to subscribers for only $6.25—a 50% savings off its regular price. This special offer is valid only during the exhibition and only while our limited supply lasts. We suggest that you order one or more copies immediately. Of course, if you are not satisfied after you have had an opportunity to examine it in your home, simply return the book and the Museum will refund the purchase price.

The 1981 NATURAL HISTORY Photographic Competition Deadline is April 1

The Grand Prize-winner this year will have a rare opportunity to photograph exotic wildlife with a close-up lens. And the winner may not even be a photographer. Let us explain about the special 1981 contest:

The Grand Prize will be an eleven-day trip, including airfare from New York and a berth on the yacht *Buccaneer,* to the Galápagos Islands. Many fearless creatures on those islands let photographers walk right up to them. The tour, sponsored by the American Museum of Natural History, will be led by two Museum scientists.

Seventeen cash prizes, totaling $3,500, will go to winners in seven categories, including a special new one, Historical Photographs. In this category, you need not be the original photographer, but you do have to own the picture and it should be more than fifty years old. So search your attic and old albums for prize-winning pictures that fit our three major categories.

The three major categories are Animals (including birds and bugs); Plants and Their Environment, and The Human Family. First prizes of $500 will be awarded in each.

In addition, Merit Awards of $250 each will go to the best entries in four categories: Photomicrography; A Sequence in Nature (up to five photographs); Historical Photographs; and Humor in

Nature. Ten Honorable Mentions of $100 each will be selected from all entries.

The winning entries will be published in the July issue of *Natural History* and exhibited at the American Museum of Natural History.

THE RULES

1. The competition is open to everyone except employees of the American Museum and their kin.
2. Competitors may submit up to five previously unpublished entries (a sequence is considered a single entry).
3. The Museum acquires the right to publish, exhibit, and use for promotion the winning photographs. The Museum assumes no responsibility for entries.
4. Entries may be transparencies or prints, either color or black and white, up to 8 by 10 inches. Each must bear the photographer's name and address. Entries must *not* be mounted in glass.
5. Enclose a self-addressed, stamped envelop for the return of entries.
6. Entries must be postmarked no later than April 1, 1981.

Pack them carefully and mail them to:

And good luck!

Nelson's Glass Eye and Other Tricks of the Trade

There is an old story told in the American Museum of Natural History about a former curator of prehistoric archeology, Nels C. Nelson, who had a glass eye. Nelson was a scientist on the Central Asiatic expedition, led by Roy Chapman Andrews, that explored the Gobi Desert in the 1920s. Mongolia, which had recently undergone a revolution, was a wild and lawless area at the time, ruled by warrior princes and crisscrossed by nomadic bands. At one point in 1925, the expedition ran into a hostile and well-armed group of Mongols on horseback, with the usual cartridge belts slung across their chests. The warriors had dismounted and were parlaying with the nervous expedition leaders when Nelson had an idea. Pretending to be a magician, he removed his glass eye, held it up for all to see, then slipped it back into its socket. The Mongols fled.

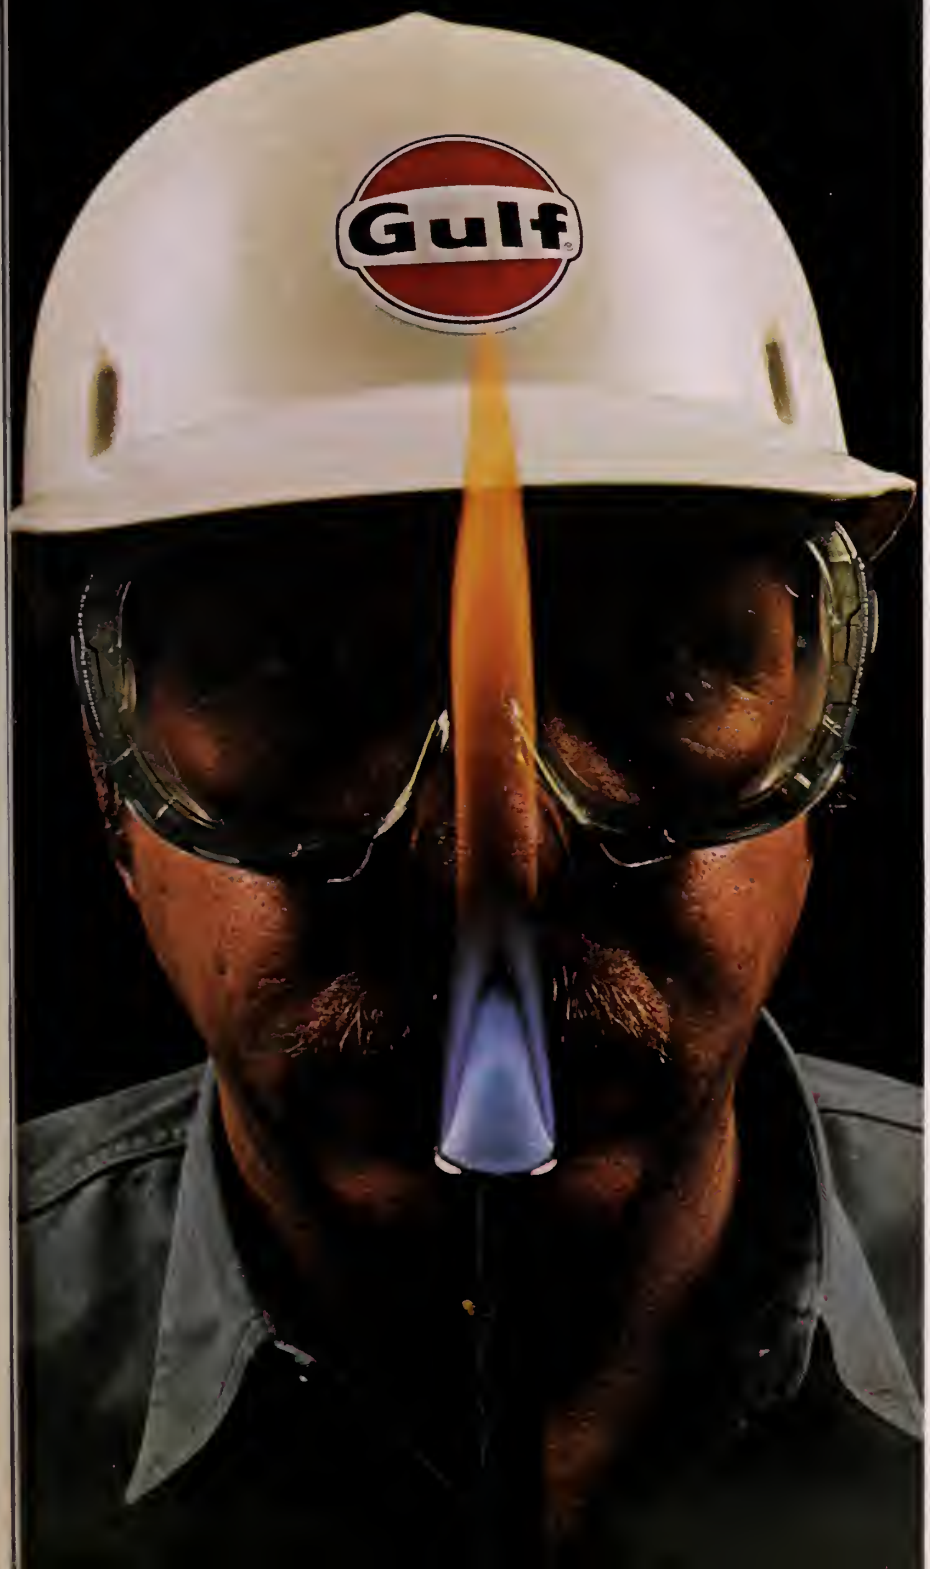
Whether the story is true or not, it illustrates an important point: Museum scientists and expeditions have had some close calls in the field, especially in countries at war.

The Jesup North Pacific Expedition (1897–1903) gave the Museum its first real taste of trouble. Organized by Morris K. Jesup, the Museum's third president, the expedition set out to explore the cultures of the entire North Pacific rim, from Washington State to Manchuria in northern China. One expedition leader, Russian anthropologist Waldemar Jochelson, was dogged and harassed by the czar's secret police while working among the aborigines of Siberia. Another anthropologist, Berthold Laufer, found himself in the midst of the Boxer Rebellion, the unsuccessful uprising against foreigners in China. In another incident, he was prevented from studying the Ainu of southern Sakhalin Island, Siberia, by a "band of desperadoes." Later, while in Manchuria, he survived the Russo-Japanese war.

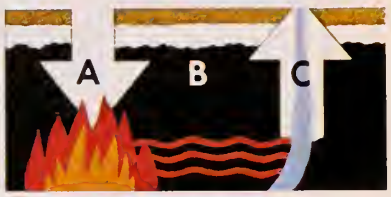
The artifacts these explorers brought back, many of which are on display in the Museum's new Hall of Asian Peoples, are priceless from an anthropological point of view. The various household, religious, and ceremonial items, sleds, clothes, art, and other objects were collected just before many of the fragile circumpacific cultures were destroyed or westernized. In many cases these items provide the only record of now vanished peoples.

The greatest difficulties in the field were encountered by the ambitious series of expeditions conceived, organized, and directed by Roy Chapman Andrews between 1915 and 1930. Although Andrews's primary goal of finding the birthplace of the human race in Central Asia was never realized, his Central Asiatic Expeditions made spectacular and important discoveries of fossils (including the first dinosaur eggs) and brought back extensive collections of archeological artifacts, ethnographic material, mammals, birds, plants, and minerals—in short, just about anything worth collecting. But there were difficulties.

During this period China was embroiled in a series of civil wars, and Mongolia was in a state of near anarchy. Nonetheless, Andrews led his caravan of camels and motorcars across thousands of miles of Central Asia, across borders, through mountain passes, and over the vast wasteland of the Gobi Desert. He armed his expedition with hunting rifles and a machine gun and packed a revolver and cartridge belt himself. He was extremely impatient with minor officials, red tape, and roadblocks. In his reports to the Museum's president, Andrews wrote that he prevented "unwarranted delays" at border crossings by telling the obstructive official that he was quite prepared to shoot his way through. This "good trick," he reported, "usually worked."



Andrews's chauvinism was typical



AMNH

Roy Chapman Andrews, at camp in Dah Ser Hai in the Gobi Desert, is visited by a Mongolian delegation. Andrews, who was recuperating from a gunshot wound at the time, was leader of the Museum's Central Asiatic Expeditions.

"How we get energy out of coal without taking the coal out of the ground."

"A lot of coal in America—millions of tons, in fact—is too deep or too slanted to be mined by any conventional techniques," says Gulf Engineer Jerry Daniel. "At Gulf, we're working with the Department

Air through injection well supports combustion of coal at A, fire heats coal at B, which produces gas recovered through production well, C.

of Energy on a way to extract the energy from that coal without mining it. We drill an injection well to set fire to the coal. By burning some of the coal, we heat up the rest, which causes it to produce gas. That's why it's called underground coal gasification.

"We had a test burn here in Rawlins, Wyoming, late in 1979, and we're setting up another one. Our hope is that by 1990, industry will be able to use this kind of synthetic gas, which of course will make us less dependent on expensive imported crude oil as an energy source.

"At Gulf, our first priority is to get all the oil and natural gas we can out of resources right here in America. But we're working on a lot of other good ideas, too. Underground coal gasification is one of them; and we're working with synthetic fuels, tar sands, geothermal energy, and other alternative energy sources.

"Overall, you might say that the business we're really in is the business of energy for tomorrow."

Gulf

Gulf people: energy for tomorrow.

Gulf Oil Corporation

"Someday we may use gas from coal the way we now use natural gas."

of his generation. Dedicated to his work, to the Museum, and to science, he believed that extreme measures to further scientific goals were necessary for the good of humanity. The concepts of tact, compromise, and diplomacy were foreign to his philosophy, but if it were not for his aggressiveness, invaluable research and priceless collections would have been lost.

Andrews cheerfully risked his life, taking excessive risks for the benefit of the expedition. On one occasion, when he had been holed up in Peking for some time and was impatient to pick up supplies at Tientsin on the coast, he attempted to drive his car from Peking to Tientsin across the front lines of two armies battling for the imperial capital. The following account of Andrews's trip is taken from one of his reports:

"On April 13 there was heavy gunfire just outside of Peking, and after a dinner at the American Minister's, we adjourned to the roof of the Peking Hotel. The machine guns showed in a steady stream of light along the southern horizon punctuated by the wide flashes of heavy guns.

"I wanted to get through to Tientsin and made a try for it the next day with three members of the Expedition—Shackelford, Hill, and Beckwith. We thought that a large American flag on the car would protect us as it had done in former years. The gates of Peking were heavily guarded, but the soldiers let us pass. Carts were already coming into the city loaded with grain, camp gear and soldiers. Cavalry streamed by and then thousands upon thousands of infantry. An officer told me that Chang Tso-lin's troops had taken Tungchow, fourteen miles from Peking, and were looting

Hopi Spirit

The Hopi have the distinction of being America's oldest, continuously surviving culture. The pueblo of Oraibi in Arizona, for example, has been in existence since pre-Columbian times. The Hopi survived the expansion of the United States into the West and the turbulent Indian Wars by dealing with, and learning from, European culture, while retaining their basic values and traditions.

Hopi Kachina: Spirit of Life, a traveling exhibition designed and organized by the California Academy of Sciences, is now on display in Gallery 3, marking the first time the Hopi have cooperated fully with a museum project. The core of the exhibition is 150 kachina figurines donated by Nathaniel Owings; these are carved by the Hopi to represent spirits known as kachinas. According to tradition, the kachinas come down every year from the San Francisco Peaks in Arizona to the dry mesas below, where they participate in the seasonal cycle of dances. Included in the exhibition are models of Hopi villages and kachina ceremonies (where the figures are used to represent human dancers), original murals, music, artifacts, and slide presentations, giving the visitor the sense of being in a Hopi village in northern Arizona during the ceremonies. The exhibition will close May 8.

Hopi Films

On Saturday and Sunday, March 7 and 8, from 2:00 to 4:00 P.M., several archival and one recent documentary on the Hopi will be shown in the Auditorium. Elizabeth Weatherford, director of the film project at the Museum of the American Indian, will introduce the films, among which are *The Snake Dance at Walpi* (1901), one of the first films ever made, and *Hopi* (1981), demonstrating the strength of the Hopi "traditionalist" way of life. The programs are free.

Hopi Symbols

A new exhibit, *Bird, Cloud, and Snake: Hopi Symbols,* will open March 10 in the Akeley Gallery. The rich fertility symbolism of Hopi art is revealed through tapestries, woodcarvings, pottery, paintings, and more. Visitors are advised to visit *Bird, Cloud, and Snake* before seeing the major exhibition in Gallery 3, *Hopi Kachina: Spirit of Life.*

The Rise of Icarus

A new exhibition, *Gossamer Albatross: The Challenge,* opens in the Roosevelt Rotunda on March 1. The *Gossamer Albatross*, piloted by Bryan Allen, was the first human-powered aircraft to cross the English Channel. Its designer, Paul MacCready, won the Kremer Prize of $200,000 for this feat. Two years earlier, Allen became the first person to achieve sustained human-powered flight when he flew a figure-eight course of more than a mile in the *Gossamer Condor.* On June 12, 1979, Allen pedaled the seventy-pound *Albatross* across the Channel in just under three hours at an average speed of eleven miles per hour. The centerpiece of the exhibit is the *Gossamer Albatross* itself. A short film depicting the historic crossing will be shown continuously. The exhibit is sponsored by Du Pont, which provided MacCready

the city but that no fighting was taking place.

"We drove on slowly, and eventually passed beyond the rear of the retreating army. For three or four miles the countryside was deserted, houses closed and all as quiet as the grave. We were five or six hundred yards from the ancient marble bridge at Tungchow when there came the sharp crack of a rifle and a bullet struck beside the front wheel. A second later a mass of soldiers appeared on the road and bullets began spattering around us like hailstones. They had opened fire with a machine gun, but it was aimed too low and the bullets were kicking up the dust just in front of us. The soldiers could see the American flag plainly enough but that made not the slightest difference.

"Fortunately at this particular spot the road was wide enough for the car to be turned and I swung it about in record time. The bullets now were buzzing like a swarm of bees just above our heads. Forty yards down the road a sharp curve took us out of sight of the machine gun. The other men crouched in the bottom of the car. Since I was driving I could see all the fun. It was a pretty rough road, but the speedometer showed fifty miles an hour as we went back. The ride became an exciting one. All the houses which had seemed so peaceful actually were occupied by the advance-guards of Fengtien soldiers. They had let us pass because of the American flag, but when they heard the firing in our rear and saw us returning at such a mad speed, they evidently thought that we were anybody's game. Each and every one decided to take a shot at us.

"For three miles we ran the gantlet

with the ultralight covering for the aircraft.

The Bene Israel

The March membership program will be *Shanwar Telis: Shipwrecked Jews of India*. The story of a small group of Jews who were shipwrecked on the west coast of India 2,000 years ago and eventually settled near Bombay is told in Johanna Spector's award-winning film *The Shanwar Telis or Bene Israel*. The program, which will describe the group's history, customs, and ceremonies up to the present day, is presented in cooperation with the American Jewish Congress and will take place on Wednesday, March 18, at 7:30 P.M. in the Auditorium; nonmembers must pay an admission fee of $3.50.

Drama 1A

A new sky show, *The Drama of the Universe*, opens at the Hayden Planetarium on March 5. In a series of short "acts," the show presents intriguing facts and discoveries and looks at recent astronomical theories. Call (212) 873–8828 for sky show times.

Toddler Tales

A program for youngsters will be presented in the Education Hall on Saturday, March 21, at 11:00 A.M. and 2:00 P.M., and on Sunday, March 22, at 1:00 and 3:30 P.M. A short play, *Tale of Two Whales*, using puppets, slides, and a film of the birth of a Beluga whale, will start the program. Children will then have the chance to color pictures and handle objects such as a narwhal tusk. The program is designed to introduce 3- to 7-year-olds to the natural sciences. Advance registration is necessary; call the Membership Office at (212) 873–1327 for more information.

Martial Arts

Capoeira is a martial art brought from Africa to Brazil, where it has been practiced for 300 years. A combination of dance, song, and ceremony that requires acrobatic skills, capoeira is performed with a great deal of somersaulting and kicking. The African-American program of the Education Department is presenting a free lecture-demonstration with Bill Moore on the art of capoeira on Sunday, March 15, at 2:00 P.M. in the Auditorium.

What Is It?

March 7 is the Museum's annual *Identification Day*. Staff members from the Museum's scientific departments will be on hand to identify and explain any and all objects you bring in, whether they be fossils, minerals, bones, feathers, baskets, cockroaches, shells, beetles, pottery, arrowheads, or beads. This free program takes place in the Education Hall from 1:30 to 4:30 P.M.

Hindu Myth

The Education Department will offer a lecture by Wendy Doniger O'Flaherty on *How to Prove That a Mythical Experience is Real*. O'Flaherty, a professor of Indian studies at the University of Chicago, will discuss the interpretation of dreams and visions using Hindu texts. The free lecture will be given on Sunday, March 22, at 2:00 P.M. in the Auditorium.

Long live the tiger!

SAVING THE TIGER

Guy Mountfort, founder of The World Wildlife Fund
Foreword by Sir Peter Scott, Chairman of The World Wildlife Fund

Beautiful and ferocious, the tiger has fascinated man for centuries, but until recently little was known of its private life. Here is the complete story—illustrated with over 100 breathtaking photos, many never before published—of the life of the wild tiger and the remarkable international campaign to save the species from extinction.

of firing from both sides of the road. I would see a soldier standing ready with his rifle at the side waiting until we came opposite. Then 'bang' he would let us have it. Sometimes they fired in squads; sometimes singly. The only reason why we were not riddled with bullets is because the Chinese soldier is the world's worst shot. Most of them aimed directly at the car, when they aimed at all, and the bullets struck just behind us. Every now and then one would zip in close to my head but no one was hit. I really had the best of it because the others could not see what was going on and driving the car kept me busy. I expected every moment that one of the tires would be hit. A blowout at that speed would have turned us over.

"Before long we could see the rearguard of the retreating army and the sniping at us ceased. Still our troubles were far from being ended. The first retreating soldiers, three of them, asked for a ride. I thought that they might be a protection and let them stand on the running board of the car. Suddenly one of them saw an officer. Without a word he stepped backward off the car, rolled on the ground with his right hand under the rear wheel. As I put on the brakes it ground his hand and arm into the hard gravel road. I have never seen such a sight; his hand was simply shredded. I put on a tourniquet to stop the bleeding but he was only anxious for us to go.

"A little farther and we came to masses of infantry. Against my protests they piled on the car in such numbers that it could pull only in first speed. The inevitable happened when one fell off, breaking his leg. Things looked pretty bad. Three or four of the soldiers worked themselves into a rage, cocked their rifles and were just about to shoot us when an officer appeared. Fortunately he could speak Mandarin Chinese perfectly (the others talked a difficult Shantung dialect) and when I explained what had happened he cleared a passage so that we could drive off the road into the fields. With much difficulty we got through the gates back to Peking."

The Chinese later seized part of the expedition's collections, and Andrews was made to understand that his collecting days in Central Asia were over.

Today Museum curators and research associates continue to experience politically inspired problems in the field, especially in countries with unstable revolutionary governments and those led by military juntas. Most scientists, naturally enough, are reluctant to discuss their experiences for fear the publicity will further compromise their research efforts; their stories will have to wait for a later day.

Even without political problems, fieldwork has never been easy. But its rewards are great; the Museum's collections would be poorer if scientists had not been willing to take risks. And even more important, our knowledge of cultures that have now vanished would be sketchy indeed.

Douglas J. Preston

A Museum expedition to Siberia led by Waldemar Jochelson in 1900 faced a variety of problems. Jochelson (standing, center) and his wife (seated) were the first whites to cross the Stanovoi Mountains. With winter coming and their horses exhausted, Jochelson built a raft and floated the party to safety.

AMNH

Fill out this coupon and save the children

Complete this simple questionnaire, and befriend a needy child through Save the Children. For only fifty-two cents a day, your money, combined with that of other sponsors, can breathe new life into an impoverished village... help hardworking people in their fight for dignity... turn despair into hope for a child who has known only disaster. Fifty-two cents may not buy much where you live. But for the poorest of the poor where the need is so desperate, it can work miracles. NH 3/1

My Name Is _____
(please print)

Address _____

City _____ State _____ Zip _____

Tell us how you want to help, by answering these questions:

1. What kind of child would you like to help?

☐ Boy ☐ Girl ☐ No preference

2. What geographical area are you interested in?

Urgent need exists in all the areas listed below, especially overseas. If you have a strong preference for a particular location, check the area of your choice. If not, won't you please let us assign a child where the need is greatest?

☐ **Certainly. Choose a child for me in an area of greatest need.**

I strongly prefer:

☐ Africa	☐ Honduras	☐ Mexico
☐ American Indian	☐ Indonesia	☐ Nepal
☐ Bangladesh	☐ Inner Cities (U.S.)	☐ Southern States (U.S.)
☐ Chicano (U.S.)	☐ Israel	☐ Sri Lanka (Ceylon)
☐ Colombia	☐ Lebanon	
☐ Dominican Republic	☐ Mediterranean	

3. Would you like a picture of your sponsored child?

Shortly after we select a child for you, we can send you a photograph and brief personal history, if you desire.

☐ Yes ☐ No

4. Would you like to exchange correspondence?

If desired, correspondence can build a meaningful one-to-one relationship and provide a unique educational experience for the sponsored child. In areas where illiteracy is high, a village representative will keep you informed of the progress your child is making. Translations, where necessary, are supplied by Save the Children.

☐ Yes ☐ No

5. Would you like information about the child's community?

Several times a year you can receive detailed reports on the activities and projects being undertaken in the community to benefit your sponsored child. These community reports show how your money is being used most effectively for permanent improvements to the child's environment—for health care, education, food production, nutrition, and community training. Would you like to receive such information?

☐ Yes ☐ No

6. How do you wish to send your sponsorship contribution?

Enclosed is my check for $_____ .

☐ Monthly, $16 ☐ Semi-annually, $96

☐ Quarterly, $48 ☐ Annually, $192

7. Do you wish verification of Save the Children credentials?

Save the Children is indeed proud of the handling of its funds. Based on last year's audit, an exceptionally large percentage (83.5%) of each dollar spent was used for program services and direct aid to children and their communities. Due to volunteered labor and materials, your donation provides your sponsored child with benefits worth many times your total gift. Would you like to receive an informative Annual Report (including a summary financial statement)?

☐ Yes ☐ No

(A complete audit statement is available upon request.)

8. Would you rather make a contribution than become a sponsor of an individual child at this time?

☐ Yes, enclosed is my contribution of $_____.

☐ Check here for general information about our unique programs for aiding impoverished children.

Padua's Botanical Garden (p. 50)

Lavishly illustrated, E.S. Hyam and W. MacQuitty's *Great Botanical Gardens of the World* (New York: Macmillan, 1969) includes an excellent chapter on the Padua botanical garden with a detailed account of its history and a description of the garden as it is today. J. von Sachs's classic *History of Botany (1530–1860)* (New York: Russell and Russell, 1967), translated by H.E.F. Garnsey and revised by I.B. Balfour, was first published in 1890. It has three major parts: History of Morphology and Classification 1530–1860; History of Vegetable Anatomy 1671–1860; and History of Vegetable Physiology. A continuation of Sachs's *History* first published in 1909, J.R. Green's *A History of Botany (1860–1900)* (New York: Russell and Russell, 1967) surveys plant morphology, anatomy, and physiology in the late nineteenth century. C. Thacker's *The History of Gardens* (Berkeley: University of California Press, 1979) is an in-depth account of the history of gardens from ancient times to the present. Lively and well written, it includes a chapter on the Renaissance garden in Italy and a description of the evolution of the modern botanical garden.

Siberian Cranes (p. 58)

A source of information on crane conservation and captive breeding projects is the International Crane Foundation's quarterly newsletter published for its members, *The Brolga Bugle*. The last three issues (January 1981, October 1980, August 1980), all available for $1.00 apiece from the foundation, at Baraboo, Wisconsin 53913, feature articles on Siberian cranes. D. Alexander's "Report from a Troubled Land" (*International Wildlife*, June 1980, pp. 45–48), a short survey of the status of wildlife in Afghanistan, tells of the headway conservationists there were making with Siberian cranes before the Soviet takeover and what has happened since. L.H. Walkinshaw's *Cranes of the World* (New York: Winchester Press, 1973), the standard text on cranes, is available in most libraries. For a general text on management techniques used for endangered birds, see S.A. Temple's *Endangered Birds* (Madison: University of Wisconsin, 1978).

Gossamer Odyssey (p. 64)

The most thorough work on the flight of the *Gossamer Condor* is M. Grosser's *Gossamer Odyssey*, scheduled to be published in May (New York: Houghton Mifflin, 1981), from which the article in this issue is adapted. Beginning with da Vinci's flying machine and ending with the *Gossamer Condor*'s success at the 1977 Kremer Competition, D. Dwiggins's *Man-powered Aircraft* (Blue Ridge Summit: Tab Books, 1979) surveys the history of human-controlled flight. A more detailed, comprehensive treatment of the subject, D. Reay's *The History of Man-powered Flight* (Oxford: Pergammon Press, 1977) includes a chapter on the Kremer Competition. Large and colorful, S. Dalton's *The Micracle of Flight* (New York: McGraw-Hill Book Co., 1977), a step-by-step investigation of how winged objects, both animal and mechanical, fly, devotes its last two chapters to the evolution of human-powered flight. M. Hewish's "How *Gossamer Condor* Was Pedalled Through the Sky to Win £50,000" (*New Scientist*, October 6, 1977, pp. 28–29) explores the aircraft's successful design, and M.E. Long's "The Flight of the *Gossamer Condor*" (*National Geographic*, January 1978, pp. 130–40) features many color photographs of the aircraft. "Winged Victory of the *Gossamer Albatross*" (*National Geographic*, November 1979, pp. 640–51) is pilot B. Allen's account of his historic flight across the English Channel.

Vermont (p. 72)

H.F. Wilson's *The Hill Country of Northern New England* (New York: AMS Press, 1967), reprinted from the 1936 edition, is a social and economic history covering the transformations in farm life in the White and Green mountains. C.W. Johnson's *The Nature of Vermont* (Hanover: The University Press of New England, 1980) is a readable history and natural history of Vermont. N. Perrin's *Vermont in All Weathers*, with photographs by S. Bullaty and A. Lomeo (New York: The Viking Press, 1973), is a personal, chatty chronicle of what Vermont life is like each month of the year; his collection of essays on country life, *First Person Rural* (New York: Penguin Books, 1980), includes chapters on fence posts, making maple syrup, and buying a pick-up truck. *Contrary Country* (Brattleboro: The Stephen Greene Press, 1961) celebrates what author R.N. Hill calls Vermont's "private flavor" and Vermonters' "trait of waywardness." *Mrs. Appleyard's Farm Kitchen*, by L.A. Kent and P.K. Campion (Boston: Houghton Mifflin Co., 1977), is a cookbook whose recipes of traditional Vermont country cooking are sometimes preceded by anecdotes of Vermont life. Folklorist J. Beck's *The General Store in Vermont* (Montpelier: The Vermont Historical Society, 1980) is a collection of anecdotes derived from her tape-recorded interviews with store owners. This paperback is available for $4.50

from the Vermont Historical Society, 109 State Street, Montpelier, Vermont 05602. This society also publishes *Vermont History*, a scholarly quarterly, and *Vermont History News*, an informal newsletter, for its members. A subscription to *Vermont Life* is available for $6.00 from *Vermont Life*, 61 Elm Street, Montpelier, Vermont 05602. Also available from them are *Vermont for Every Season* (Montpelier: *Vermont Life* Magazine, 1980), a collection of essays on specific times in Vermont, such as peak season (during the height of the fall foliage) and mud season; and *Justice in the Mountains* (Shelburne: New England Press, 1980), D. Davis's account of his career as a Vermont country lawyer, judge, and, finally, governor of the state.

Dead-Tree Insects (p. 84)

Intended as a basic exposition of ecology for the beginner, R.E. Ricklef's textbook *The Economy of Nature* (Portland: Chiron Press, 1976) includes chapters on community diversity and energy flow. Ricklef's earlier book, *Ecology* (Portland: Chiron Press, 1973), an 881-page study, is broader and more comprehensive. Part 8, "Community Ecology" (pp. 589–780) interprets the patterns that occur at the community level in terms of ecological and evolutionary processes at the population level. More specific references on insect–deadwood ecology are H.E. Savely's "Ecological Relations of Certain Animals in Dead Pine and Oak Logs" (*Ecological Monographs*, July 1939, pp. 322–85), and S.A. Graham's "The Felled Tree Trunk as an Ecological Unit" (*Ecology*, October 1925, pp. 397–411). These well-written, still relevant articles are easy to follow and available in most libraries.

Rita Campon

If you'd like a poster of these two gentlemen for your bar, drop us a line

JACK DANIEL AND HIS NEPHEW, Lem Motlow, disagreed on most everything. Until it came to making whiskey.

Mr. Jack (that's him on the left) was a fancy dresser. So Lem refused to wear a tie! But they both insisted on mellowing their whiskey through huge vats of charcoal before aging. And we're about the only distillery who still does it that way today. You see, Mr. Jack once said, "Every day we make it, we'll make it the best we can." And neither Lem nor anybody else ever disagreed with that.

CHARCOAL MELLOWED DROP BY DROP

Tennessee Whiskey • 90 Proof • Distilled and Bottled by Jack Daniel Distillery

Blueberry Blues

Although it tastes better, the lowbush berry is more difficult to harvest and more expensive to produce

by Raymond Sokolov

photographs by Adelaide de Menil

Passing through Washington County, Maine, in August, even the least-informed traveler knows that he is in the right place for cheap, fresh lobster and that he cannot go any farther east in the United States than this bleak, coastal pocket of poverty. The alert visitor also notices that many apparently abandoned fields are littered with string. That's how it looks at first. Then it becomes clear that the string has been purposely arranged, stretched in a pattern of roughly parallel lines. Sometimes, people are hunched down along those lines of string. Watch long enough and the people move, slowly making their way down the string rows, and then heading back to the road, to blue machines set up on the shoulder. The machines are for winnowing, and the people are picking blueberries, but the neophyte wonders, "Where are the blueberry bushes?"

Those accustomed to highbush blueberry shrubs (*Vaccinium corymbosum*), which grow as tall as six to eight feet, have to look twice before they make out Maine lowbush plants (*V. angustifolium*), flourishing at ankle level, camouflaged by grasses, alder shoots, and sweet fern. The berries themselves are tiny, roughly half the size of the cultivated highbush fruits sold in supermarkets. Lowbush berries are almost never sold as whole, fresh fruits outside New England and they are not cultivated in the normal sense of the word, that is, planted by man from a selected stock. Lowbush berries are wild, naturally occurring, not adapted to mechanical harvesting, difficult to ship or store fresh, and generally impractical. But they are superb berries, tastier by far than the comparatively insipid highbush cultivars grown commercially in Michigan and other states with more hospitable climates.

Highbush plants and the even taller rabbiteye blueberries (*V. ashei*) grown in the Southeast have two crucial advantages over the undeniably more delicious lowbush fruits. Because of selection and hybridization begun by U.S. Department of Agriculture botanist Frederick V. Coville in 1909, the cultivated berries are very large and therefore appealing to consumers, who tend to taste with their eyes. Furthermore, highbush plants are high. Machines can harvest them easily and, perhaps more important, each plant can be picked selectively several times, so that only perfectly ripe berries are taken during each pass. This means that markets get an ideally uniform crop. Lowbush shrubs, on the other hand, can only be harvested once because the hand rake takes all the berries as it combs through the brush. Pickers have to wait until all the berries in a given patch have ripened. By the time this happens, the early-ripening berries on each plant are turning senescent, getting soft. Rough handling from the rake and the winnowing machine, which separates the berries from the leaves and stems pulled in by the rake, further degrades the appearance of the berries and diminishes their keeping quality.

These factors have seriously reduced the lowbush berry's appeal as a marketable fresh fruit. Also, the big Maine blueberry companies, located

at the edge of vast, flat stretches of blueberry patches known as the Barrens, have had little incentive to bother with shipping the lowbush berries fresh, for they have traditionally been able to sell almost the entire crop to large baking companies for use in muffins as well as muffin and pancake mixes. Even the mass market consumer prefers the little lowbush berry in his muffins. Unlike the bigger highbush berries, which turn into large blue blots when baked, lowbush berries don't look messy after baking, and the manufacturer can put more of them in each muffin—an advertising plus.

Recently, however, even the baking industry has been forced to look with increasing favor on the highbush berry. Lower production costs make the bigger berries roughly thirty cents a pound cheaper. Moreover, besides yielding berries that are easier to harvest and clean, highbush blueberry bushes are far more efficient producers than the wild Maine species. In Michigan, growers have been able to pick an average of two to three tons of berries per acre every year. In Maine, the average yield is only 800 to 1,000 pounds per acre every other year, and most of those acres have to be as laboriously tended as if they were conventional cultivated fields.

"I don't know what they mean when they talk about Maine wild blueberries," says Mary Ellen Bailey, an independent blueberry producer based in Columbia Falls, Maine. "We fertilize. We mow out weeds. We run oil burners over the fields."

Indeed, the only thing "wild" about Maine blueberry production is that the plant propagates itself, spreading its rhizomes underground and producing its own seed. Growers encourage the process with a battery of land-management techniques designed to reduce competition from other plants and from pests, as well as to improve the vigor of the blueberry plants themselves.

Native blueberry fields are really forests artificially held back at the low-shrub state of old-field succession by weed control. After the harvest, growers burn over their fields, a process that eliminates all surface growth but that leaves the blueberry rhizomes unharmed below ground. In effect, moreover, the burning prunes the blueberries and spurs their growth.

Meanwhile, birds spread new seed over the cleared fields, and established rhizomes take over more territory. By July, new growth begins to show above ground. Buds appear but do not blossom in the first year. Because of this biennial cycle, growers rotate their harvests so that only half their fields are in the nonfruiting stage at one time. Yearling shrubs turn red in the fall. Then growers hope for a good snow cover, which will shelter the plants from freezing winter weather. Finally, in the spring of the second year, they have the pleasure of seeing their blueberries blossom. Each bud puts forth several white or pink-tinged blossoms in late May or early June.

At this point, growers have to contend with various pests and diseases, the worst of which is the blueberry maggot. Its larvae attack the berries and feed on their flesh. To eradicate the larvae, many growers spray infested fields at the end of June.

By the end of July, the lowbush blueberry crop has ripened. Day after day, local people—schoolteachers, students, whole families—collect in the fields early in the morning, stooping over the bushes with the short-handled rakes that resemble cranberry scoops. Made from galvanized metal,

To harvest the delicious lowbush blueberry, pickers must spend long hours stooped over the rows of ankle-high plants. A rake of galvanized metal, top right, is used to pull the berries off the bushes.

these tools have long, thin teeth and a reversed handle that extends over the teeth, so that when the picker tilts a rake, berries roll into a collecting area at the back. One Abijah Tabbutt of Columbia Falls invented the blueberry rake in 1883. The first one, designed for the rough ground of unimproved fields, had only eight teeth. On today's flatter fields, on the Barrens, pickers use rakes with forty to sixty teeth. Tabbutt's grandson Clarence Drisko carries on the business at 86, selling most of the 3,000 rakes he produces in a year to the giant blueberry companies, Jasper Wyman of Millbridge and A.L. Stewart and Sons of Cherryfield.

Both companies bus in Micmac Indians from Nova Scotia for the harvest, but many of the pickers are Washington County residents earning extra cash for back-to-school clothes or for plain subsistence in the bleak economy of rural Maine. On the Barrens, where picking conditions are ideal, a large family can make up to $400 a day. But the work is very hard and a complete anachronism in the general context of American agriculture. The largest machine at a picking site is the winnower, which is a portable conveyor belt device usually run by a lawn mower motor. Some are still operated by hand.

"Every year for fifteen years, I've stood on the Barrens and said to myself, 'I don't believe that people will pick 20 million pounds of blueberries like that,' " says Amr Ismail. Dr. Ismail, an expatriate Egyptian, is no casual observer of the lowbush blueberry scene. He is the Maine Blueberry Professor of Horticulture at the University of Maine in Orono. Ismail also supervises the Blueberry Hill Environmental Farm, a research facility in Washington County. There, in scientifically managed, mulched plots, this exuberant, rotund botanist and a small team of colleagues are developing lowbush blueberry clones that will produce a bigger crop of berries than the average wild types. More important, these clones are lowbush cultivars. At Blueberry Hill, there is now actually a cultivated patch Ismail has developed. The clone spreads slowly, taking a decade to cover a field. But Ismail says that

"this may be the future. Perhaps we will compromise and go to existing fields to put desirable clones in open places left by herbicides." He also anticipates that, as the cost of hand picking rises, "they'll invent a picking machine." In fact, the University of Maine has already developed a rake head suitable for machine harvesting on level fields that are weed free.

In general, Amr Ismail is an optimist. He sees a bright commercial future for lowbush blueberries although he concedes that "once we get to propagating and planting, we won't be dealing with the native, natural plant any more." Ismail, of course, has faith in his clones. But Tom Rush, general manager of A.L. Stewart and Sons, thinks hard times are ahead for the lowbush blueberry. He told the *Wall Street Journal* that by 1985 half of all Maine growers will be forced out of the blueberry business by low prices. Ismail and Rush may actually be talking about a similar future, since only well-capitalized blueberry operations will be able to survive in a market dominated by Ismail's cultivated clones.

The ordinary consumer should be concerned about the future of *Vaccinium angustifolium*, but there is really no legitimate position for most of us to take, except to hope that the cultivated lowbush berries of the future will continue to taste as good as the experimental varieties I sampled at Blueberry Hill. For the time being, the only sensible thing is to cross your fingers and make the trip to Washington County in August to taste the quintessential American berry in the only place you are sure to find it fresh.

Once you are in Maine, you can even arrange to pick your own berries. For me, this foraging, which is almost always technically a trespass on somebody's land, is one of the most exhilarating things to do in the outdoors. Robert Frost caught the beauty and mild mischief of it in his horticulturally precise poem, "Blueberries":

> You ought to have seen how it
> looked in the rain,
> The fruit mixed with water in
> layers of leaves,
> Like two kinds of jewels, a
> vision for thieves.

Raymond Sokolov, a writer with an interest in the history and preparation of food, is editor of Book Digest.

Blueberry Muffins
(Adapted from a recipe submitted to *All Maine Cooking*
[edited by Ruth Wiggin and Loana Shibles, Courier of Maine Books]
by the late Margaret Chase Smith, senator from Maine)

- 1½ cups fresh blueberries
- 1½ cups flour
- ½ teaspoon salt
- 3 tablespoons sugar
- 1 tablespoon baking powder
- 1 egg, lightly beaten
- ¾ cup milk
- 3 tablespoons melted shortening

1. Preheat oven to 400 degrees.
2. Wash the blueberries and drain thoroughly.
3. Sift together the flour, salt, sugar, and baking powder.
4. Stir the beaten egg and milk together and then stir into the flour mixture. Add berries and melted shortening.
5. Mix well and pour into a greased muffin tin, filling each compartment three-quarters full.
6. Bake for 20 minutes.

Yield: 9 to 12 muffins

Beth and Millie Gardner's Baked Blueberry Pudding
(Adapted from *Cutler Cookery*,
United Methodist Church, Cutler, Maine)

- ½ cup plus 1 tablespoon shortening
- Salt
- ½ cup brown sugar
- 2 cups blueberries
- ½ cup white sugar
- 1 egg, lightly beaten
- ¼ cup milk
- 1 cup flour
- 1 teaspoon baking powder
- Whipped cream

1. Preheat oven to 350 degrees.
2. In a saucepan, combine 1 tablespoon shortening, a pinch of salt, and the brown sugar. Cook over medium heat until the sugar melts. Then stir in the blueberries and pour mixture into a greased baking dish.
3. Beat together the remaining ½ cup of shortening with the ½ cup white sugar until smooth. Then beat in egg and milk.
4. Sift together flour, baking powder, and ¼ teaspoon salt. Mix with mixture from step 3 to make a batter.
5. Cover blueberry mixture with the batter and bake for ½ hour. Serve with whipped cream.

Yield: 8 portions

JETTA. 4 IN THE FRONT. 8 IN THE BACK.

Compare the relative merits of today's family cars, and you'll find that a trip to your relatives would be a lot nicer in a Volkswagen Jetta.

In the front, for example, there's room enough for a family of 4 to actually stretch out and enjoy the ride.

In back, there's a trunk big enough to handle 8 suitcases. (Something you don't even get with a Rolls-Royce.)

And under the hood, there's a CIS fuel-injected engine powerful enough to take you from 0 to 50 in just 9.2 seconds. As well as around any trucks, onto any highways and up any mountains you meet along the way.

What's more, even though Road & Track has said it "will embarrass a lot of cars costing a lot more" with its performance and handling, Jetta will never embarrass you at the gas pump.

It gets an EPA estimated 25 mpg, 40 mpg highway estimate. (Use "estimated mpg" for comparisons. Your mileage may vary with weather, speed and trip length. Actual highway mileage will probably be less.)

And it gives you front-wheel drive, rack-and-pinion steering, all-independent suspension and classic European styling.

Impressed with Jetta's relative merits?

Your relatives will be, too.

Chrysler's K cars beat Ford Escort, Ford Granada, Mercury Lynx and Oldsmobile Cutlass Diesel after 50 tough Motor Trend test evaluations.

This year, the Motor Trend Car of the Year finalists were rated on more than 50 counts of performance, quality, comfort, and design. A 75-mile torture course, with every driving condition from freeways to twisting mountain roads, was used to evaluate the quality of ride and drive. And a panel of Motor Trend experts rated the cars on passenger comfort, styling and design, and dollar value. When the results were in, the K cars had outscored the Ford and GM contenders on an overall point basis. Everything you want in a new car, Motor Trend found in the K cars.

41 25* $5,880**
EST. HWY. EPA EST. MPG

*Use EPA est. mpg numbers for comparison. Actual mileage may differ depending on speed, trip length and weather. Actual highway mileage probably lower, CA mileages lower.
**Base sticker prices. Sticker prices differ in the states of CA, HI, NB, LA, NJ, MA, WA, PA, MS. See your dealer for details. Standard equipment levels vary among cars. Destination charges, title and taxes extra. WSW tires $51 extra on Reliant, Aries.

The New Chrysler Corporation

Dodge Plymouth

"In this part of the new decade, passenger comfort, ride and drive, styling and design... and most important, dollar value... are more relevant than all-out performance. In these classes, the K car simply outscored its competition; and in three cases out of four, the competition turned out to be another K car. This accomplishment alone was enough to make it Car of the Year."

Varietal wines from Taylor® California Cellars.™ Better wines. Judge for yourself.

James Allaway is a senior planner with the Land and Resource Planning Section of the Alaska Department of Natural Resources. Prior to this line of employment, he studied elephants in the lower Tana River region of Kenya. He writes that "there's a joy and exhilaration you get from elephants." He doesn't explain what he gets from working in the far north. Allaway earned his Ph.D in natural resources from Cornell University and has worked as a Peace Corps volunteer in Somalia.

As a doctoral candidate in clinical psychology at Harvard University, **Kirk Felsman** is seeking to understand how some children make healthy adaptations to conditions of severe environmental stress. His studies grew out of clinical work with children from low-income welfare families in the Boston area during which he was taken with the children's "repeated displays of strength, courage, and resiliency." Two films that deal with children who survive on the streets of major cities in Latin America led Felsman to spend a year in Colombia learning about the "gamins." The article in this issue of *Natural History* is based on that field research.

John A. Wood is a staff scientist at the Smithsonian Astrophysical Observatory in Cambridge, Massachusetts. His work on meteorites is focused on "the form and sources of the earthy materials that came to be incorporated in the solar system and the way these materials were processed and rearranged as they were being assembled into planets." Wood has also studied lunar rock samples to learn "how the materials of a small new planet first sorted themselves out into layers that are characteristic of the structure of planets."

Britain is a bargain with British Airways' Dollar Stretching Holidays.

"Once, Eliza Doolittle sold flowers here. Now, it's just bloomin' fun." *–Robert Morley*

Covent Garden. Where Professor Higgins spotted Eliza Doolittle and bet Colonel Pickering he could make her a Fair Lady. Covent Garden was then a busy marketplace of flower carts, fruit and vegetable stalls, and social activity spilling into the surrounding streets.

Today, Covent Garden survives as an amazing array of specialty stores, theatres and restaurants. Isn't it lover-ly!

Give Your Wallet A Well-Earned Rest. A 7-day "London Without Cash" holiday costs just $569 prepaid plus airfare, and includes almost everything. Room and bath at a nice, centrally located hotel. Continental breakfasts. Hearty lunches at your choice of over 100 restaurants and pubs. Elegant dinners at some of London's poshest spots. Unlimited bus and subway travel. Theatre and cinema tickets. Museum admissions. A nightclub show. A tea party. We've even included a banquet for you! Plus the morning newspaper, nightly nightcap, even postcards home.

Getting About Britain. On British Airways' "Britain Hoteltour," you can stay at a different inn every night, if you like. And you'll have a car to get you from one to the other, and to roam the countryside. Unlimited mileage. (You pay for petrol.) 7 days of travel adventure for just $279 plus airfare. Tour prices are per person, double occupancy.

Or, be on your own, in a Godfrey Davis car with unlimited mileage rented from British Airways. As little as $129 a week. (Petrol on you.) There are 160 rental locations throughout England, Scotland and Wales.

To learn about more British bargains, send the coupon for our free brochures. Then see your travel agent.

Better Than Jogging

NordicTrack

Jarless Total Body Cardiovascular Exerciser Duplicates X-C Skiing for the Best Motion in Fitness

This revolutionary new exerciser duplicates the smooth, rhythmic, total body motion of X-C skiing for the most effective cardiovascular exercise obtainable. Uniformly exercises more muscles than any other exercise device. Makes high heart rates easy to obtain and keeps more muscles in tone. Also highly effective for weight reduction.

Completely jarless natural motion does not cause joint and back problems as in jogging or running. Arm and leg resistances are separately adjustable for maximum effectiveness. The NordicTrack uses no motors and folds compactly for convenience. Used in homes, businesses, and institutions. Our customers include Xerox Corporation, US Army, Penn State U and the YMCA.

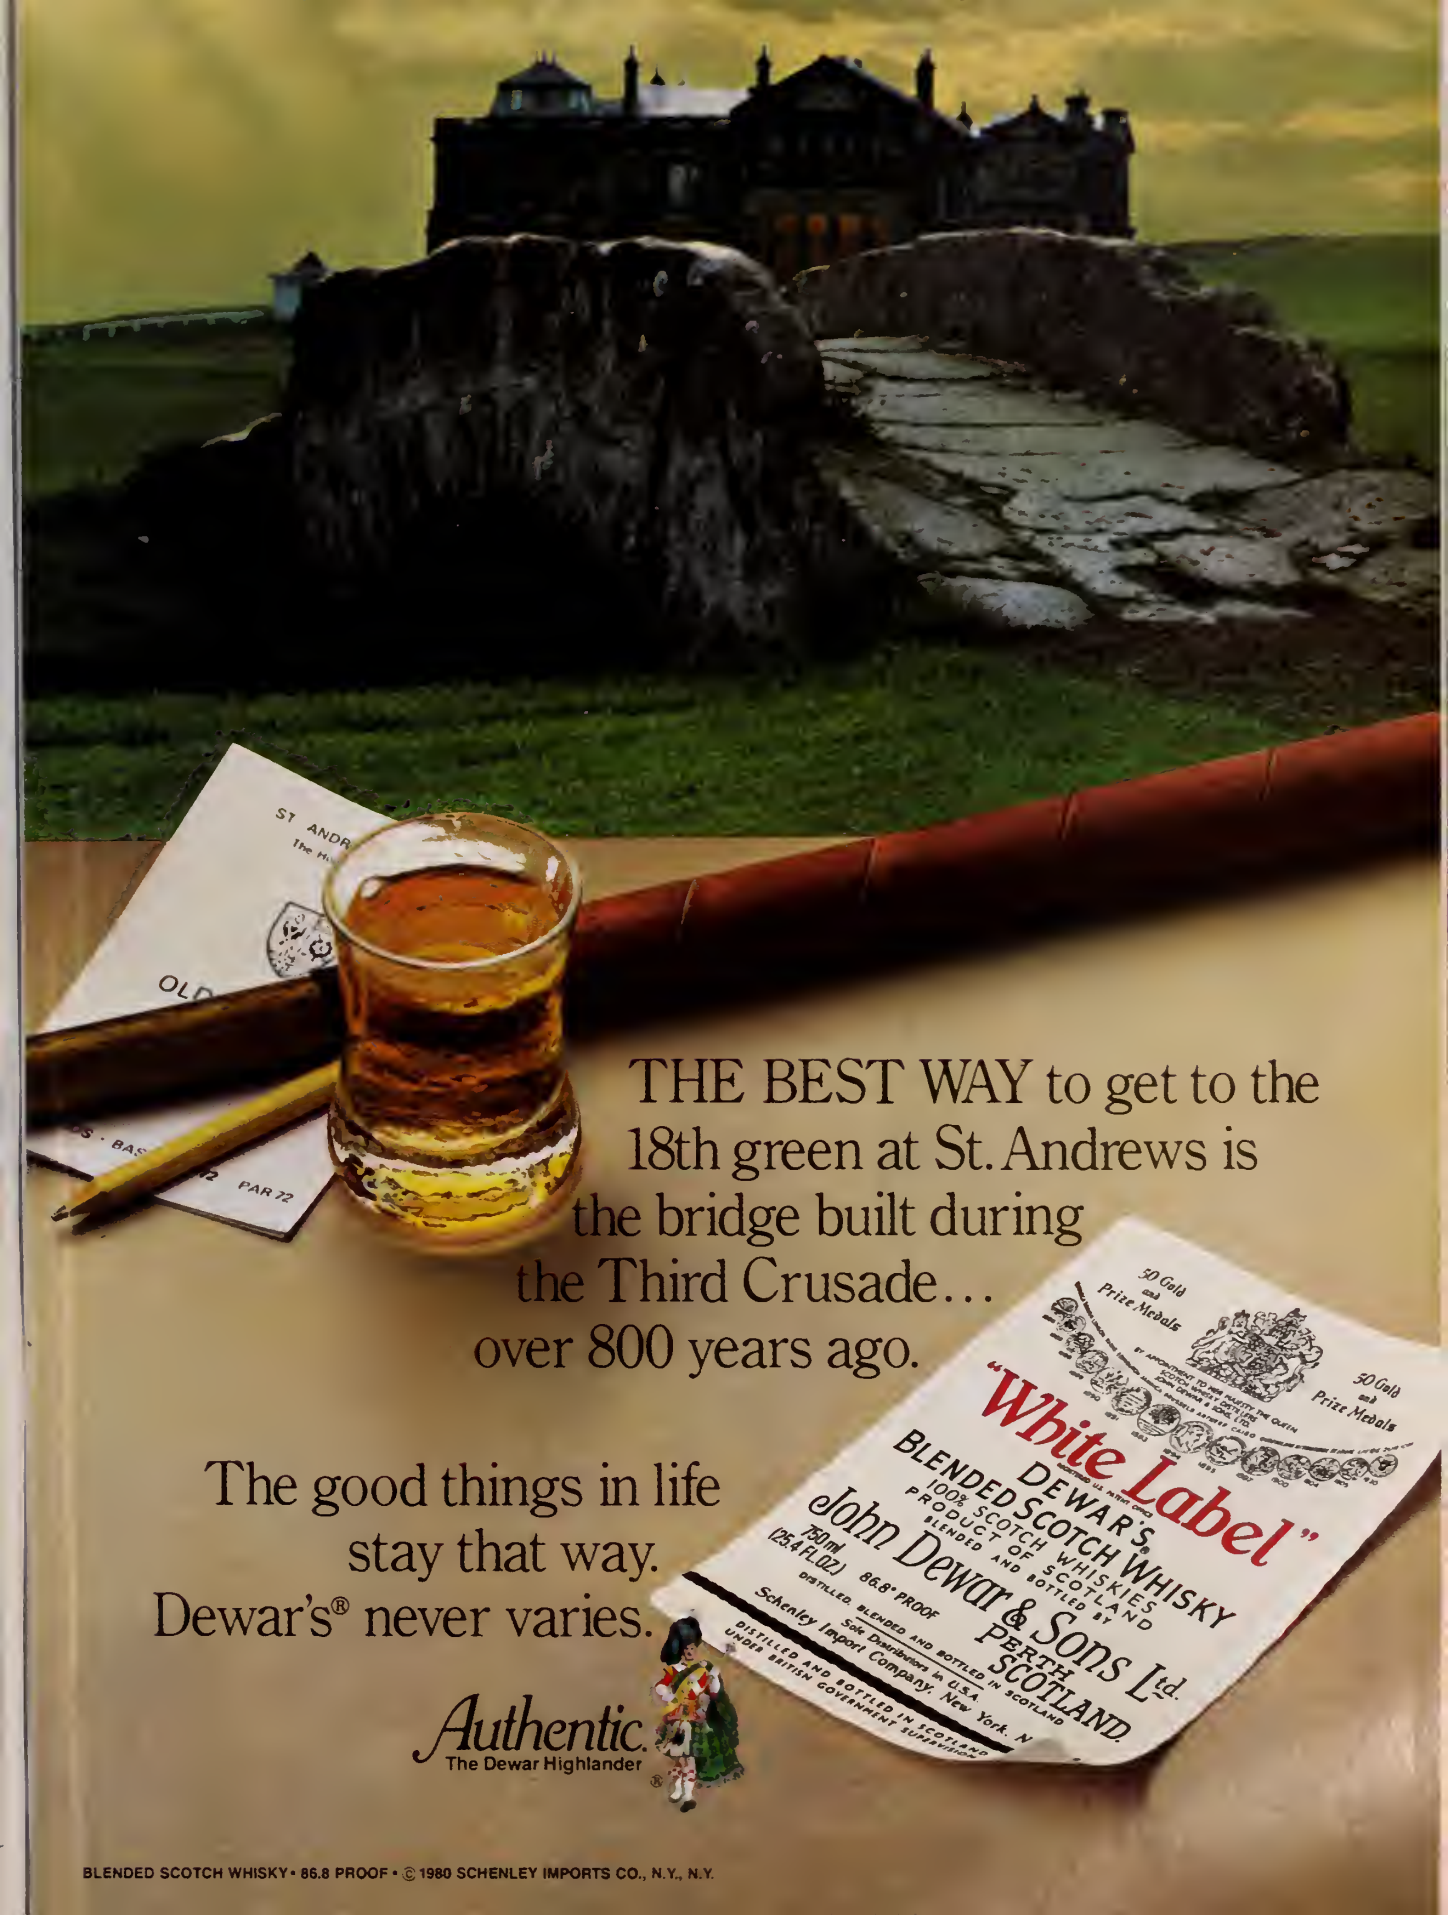
Brian Mason is curator of the Department of Mineral Sciences at the Smithsonian Institution in Washington, D.C. Born in New Zealand, he took his Ph.D. in mineralogy halfway across the world at the University of Stockholm. His interest in meteorites dates from his days as a graduate student and has caused him to concentrate on that subject for the past twenty-five years. Before going to the Smithsonian in 1965, Mason was chairman of the Department of Mineralogy at the American Museum.



Lawrence Grossman is associate professor of geochemistry in the Department of the Geophysical Sciences and the Enrico Fermi Institute at the University of Chicago. A specialist in cosmo- and geo-chemistry, he has been a NASA consultant on lunar data and the *Mariner* Jupiter orbiter, and has lectured at the Field Museum of Natural History. One of his areas of research is the chemical and isotopic compositions of the different petrographic components of chondritic meteorites as clues to the behavior of the elements during the condensation of the solar system.

Donald E. Brownlee is associate professor of astronomy at the University of Washington in Seattle, where he earned his doctorate. His current research is directed toward the analysis of interplanetary dust from the stratosphere, coral atolls, and the ocean floor. Pursuit of that work has involved "many nights in cold observatories and an oceanographic cruise from Acapulco to Hawaii to collect cosmic dust." Most of the year Brownlee lives on a houseboat on a Seattle lake, but he also "feels a strong attraction to mountains, beaches, sand dunes, palm trees, and penguins."

Marriage—Lebanese Style

Among members of the Druse sect, the marriage contract is a customary safeguard for women

by Paul D. Starr and Nura S. Alamuddin

With the women's liberation movement in the Western nations has come the proposal that couples entering into marriage negotiate an extensive contract that specifies the nature of their relationship. These agreements may include any of the financial or personal aspects of a marriage—the wife's use of her maiden name, birth control methods, whether or not to have children (and if so, the number), residence patterns, the division of household labor, the use of income, sexual rights and freedom, relationships with in-laws, and the distribution of property should the marriage end. All such provisions may not be legally binding but they can, it is argued, help us to examine the incomplete assumptions we hold about our intimate relationships and make them more equitable, satisfying, and enduring.

Marriage contracts in the industrialized West have been negotiated by a relatively few avant-garde couples, and their use strikes many as a passing fashion brought on by the push for sexual equality. But in the Middle East and other parts of the world, marriage contracts have been used by many people for hundreds, even thousands, of years.

In spite of the continuing reliance on marriage contracts throughout the Middle East, few analyses of what these agreements mean to those who use them have been possible. Shortly before the most recent Lebanese civil conflict, however, we were able to examine a large sample (3,398) of the marriage contracts negotiated by members of the Druse sect in that country from 1931 through 1974.

One of Lebanon's numerous religious sects, the Druse are also an important Arab minority group in neighboring Syria and Israel. They have continually played an important role in the history of the Levant and from the sixteenth through the eighteenth century were one of the most powerful groups in the region. Originally emerging from the sectarian turmoil of eleventh-century Cairo, the theology of the Druse includes many features that distinguish it from the mainstream of Islam. Aside from the monogamous marriage practices of the Druse, however, their contemporary way of life reflects traditional values found among most other Arab Islamic groups in the Middle East. In fact, although polygamy is permissible in other Islamic groups in the region, fewer than 3 percent of the husbands who can legally have more than one wife at the same time do so. In most respects, then, Druse marriage patterns reflect values that commonly prevail among Moslems in the Levant.

The marriage contract plays a fundamental part in the institution of marriage among the Druse. Legalizing the union, and giving it a religious sanction, a contract is usually the product of lengthy and elaborate negotiations on the part of a couple's senior kin. Some of its provisions involve only the initial establishment of the union, while others serve to help perpetuate the union or cope with its termination. The standard contract form that has been used in recent decades by the Central Druse Religious Court in Beirut includes the names, birthplaces, birth dates, and home villages of the bride and groom; the names of their fathers, deputies, and witnesses; and a place for seals and signatures. It also specifies the physical status of the bride and whether she is a virgin, a widow, or a divorcée. (Given the very strict puritanical code of the Druse, it is unthinkable that a woman could be listed as a nonvirgin and not have been previously married.) The most important part of the contract deals with the *mahr*, a payment made by the husband to the bride or her kin. There are two types of *mahr*. The first, or immediate, type is to be given before, during, or shortly after the contract-signing ceremony, and usually includes some money and such gifts as jewelry, furniture, and a sewing machine. The second, or deferred, *mahr* is a cash amount that the groom and his family agree to pay the bride in the event that he divorces her or dies before she does. Should a woman initiate a divorce, she would commonly forfeit the deferred sum.

Mahr can serve different purposes. Some regard it as purchase money, while others view it as a symbol, a ritualistic demonstration of the groom's esteem for the bride. Clearly, immediate *mahr* in the form of furniture, clothing, a sewing machine, or other goods is helpful in establishing the couple's household. The deferred *mahr* can be regarded as a kind of insurance policy to help protect the wife from the economic deprivation that she would be likely to suffer through the loss of her husband by either divorce or death. Deferred *mahr* can also reflect the degree of the husband's commitment to his spouse. Even though it is legally relatively easy for a man to obtain a divorce in the Middle East, this course of action becomes less likely, especially among rural peasants, if a husband is required to pay a large lump sum as compensation. As with so many other social inventions, the reasons for the existence of *mahr* can be as varied as the uses to which it can be put.

Given the significant role *mahr* plays during negotiations preceding a match, as well as throughout a marriage, we chose to focus our inquiry on how various characteristics of the couple influenced the amount of deferred *mahr* agreed upon.

We looked initially at how the "physical status" of the bride affected her position in the "marketplace." Vir-

You wouldn't hang a Picasso in the closet. You'd show it in its best light. Proudly. Leica feels the same way about photography. It would be a pity if pictures taken with our amazing R4 weren't projected with our equally amazing Pradolux* RT300. Each is superb. Together, incomparable.

Consider the Leica* R4: the camera that's so automatic, so responsive, it can do everything, simply. It's the only camera in the world with two independent light meter systems. You can select either full-area (averaging) or selective (spot) metering with a touch of the controls. And you have multi-mode exposure automation working with the two metering systems. Again truly unique. This gives you shutter priority, aperture priority, programmed control, metered manual and flash automation in fractions of a second. And you have a full system of accessories including motor drives and the incomparable Leica-R lenses to bring all this potential to actuality, simply.

The only slide projector made to this high standard is our own: the Pradolux RT300. It offers Leica lenses in a full range from 60 to 200mm in both curved and flat-field configurations. The internal condensers are just as important as the lenses. That's why ours are Leica optical quality, too. You can count on high efficiency cooling for long life of the projector, the lamp and your slides. The Pradolux RT300 accepts Kodak Carousel* trays and stack loaders. Plus a range of built-in features that seems to go on forever.

In fact, with both the Leica R4 camera and Pradolux RT300 slide projector you will see how impressive your images really are. Pablo. Ask your dealer for information, or write E. Leitz,* Inc. Dept. NH-4, Rockleigh, N.J. 07647.

Leitz

Leitz means precison. Worldwide.

gins were seen worthy of a much higher *mahr* than either widows, divorcées, or those described as *thayyib* (literally, "nonvirgins," also referring to widows and divorcées). The inferiority of previously divorced brides, as reported to us by various Druse informants, was apparent. Their *mahr* was less than a tenth of that for virgin brides, and less than half of that for either widows or *thayyib* women.

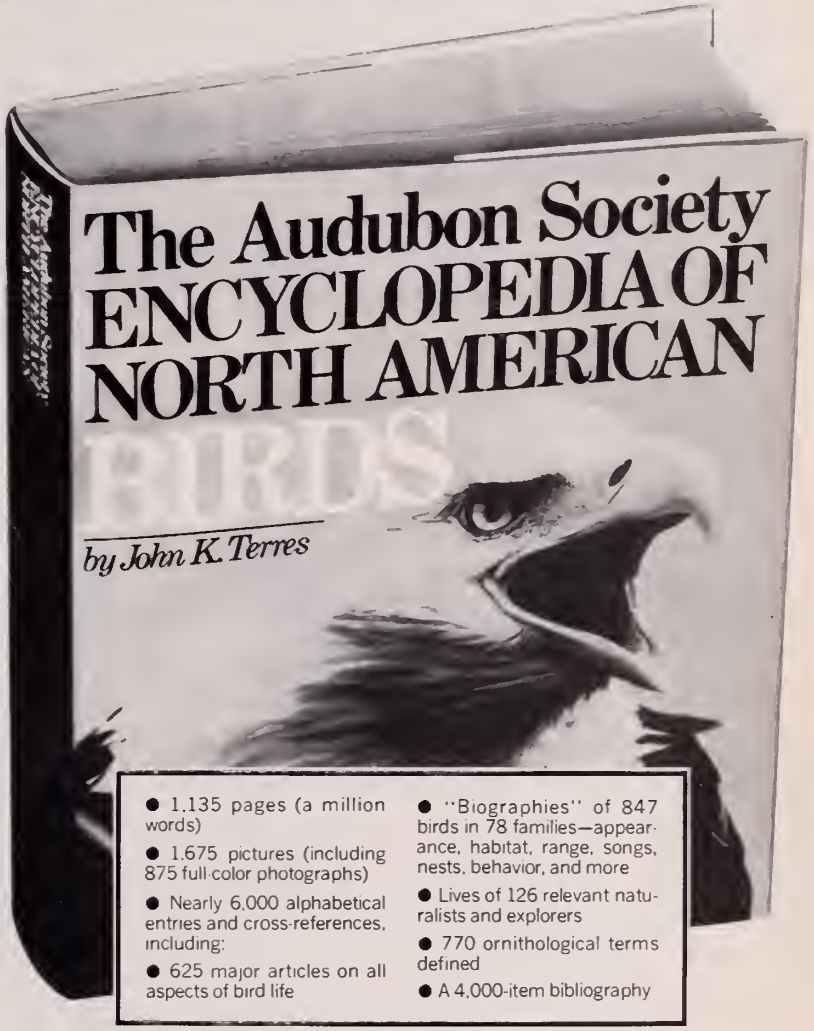
We looked next into the effect that the social standing of the couple's families had on *mahr*. Traditionally, Druse families are either of the sheikly class or are commoners. This distinction, based on the historic exploits of ancient nobles and warriors, is commonly known and accepted within the sect. The great majority of Druse marry within their class, with sheikly unions specifying a higher *mahr* than those between commoners. If a man of high status marries a commoner, however, he pays much less than he would for a bride from his class. Most interesting is the very high *mahr* a commoner agrees to pay for a sheikly bride. In the few instances in which a commoner has gained the hand of a sheikly bride, he has paid a high price for the status that his partner brings to the marriage. When a high-status groom has a commoner bride, however, the status he confers upon her is presumed to be an ample reward. He agrees to pay a little more than half the *mahr* given a sheikly bride.

Status is not the only social boundary that influences marriages among the Druse. As with many other Middle Eastern groups, their families have historically belonged to larger political factions. The Druse have two basic factions, the Yazbaki and the Jumblati, with a small minority of families maintaining an affiliation with both. These groups have historically been at odds over issues within the community and have often been in opposition on the larger national scene. Each has been allied with opposing coalitions made up of other Lebanese Christian and Moslem groups. Reflecting the increased liability that cross-factional marriage entails, the average *mahr* for such a match is significantly higher than a marriage within either the Yazbaki or the Jumblati faction. The lowest *mahr* was found in marriages between families that had ties to both political factions, presumably because these marriages should be less affected by internal political turmoil.

Endogamy, the custom of marrying within a particular group, is a basic feature of Middle Eastern marriages, with the strongest preference for unions between a man and his father's brother's daughter. If the most desired form is not possible, the preference is for matches within the same clan. To determine how the satisfaction of these preferences might affect the amount of *mahr* agreed upon, we examined how it was influenced by the couples being related and by their residing in the same area.

We found that marriages within the same clan had the lowest *mahr*, suggesting that the perceived liability for such matches was also low. Surprisingly, however, closeness in terms of the physical proximity of two families resulted in a lower *mahr* than did closeness in terms of kinship. For example, when the couple's families were related but separated by long distances, as in the case of a wedding between one branch of a clan that lived in Syria and another branch that lived near Beirut, the average *mahr* was much higher than when the families were unrelated but living in the same village. The conclusion that physical proximity is more desirable than closeness in terms of kinship and may promote a better marriage was also shown in other situations. Among the highest average *mahrs* were those that involved the greatest physical separation of the bride from her family, as in the case of women going to marry Lebanese immigrants living in Australia or the United States. Obviously, the greater the distance a bride is from her family, the less they are able to aid her. To compensate for this disadvantage and to increase her protection, a larger *mahr* is sought.

Observations and discussions with Druse of a variety of backgrounds indicated that personal characteristics of the potential mates, as well as those of their respective families, also produced variations in *mahr*. It is common for undesirable suitors to be turned down in a diplomatic way by demanding an exceptionally high *mahr*. If a suitor is seen as "too old" for a woman, is divorced, or has a reputation for being unstable or unreliable in some respect, a woman's parents will usually seek a very high *mahr*, to get him either to withdraw or to provide a considerable amount of "insurance" for their daughter. The general physical attractiveness, intelligence, education, and personality of those involved are also important. A highly desirable match from the point of view of the couple and families involved is seldom lost because of a lack of agreement about the *mahr*.



The contracts had no details about most of the personal characteristics of those married but did include their ages. This enabled us to see how differences in the ages of the bride and the groom affected the amount set. Conventionally, Druse men marry women who are about seven years younger than themselves. We anticipated that significant departures from this norm would result in a higher *mahr*. The actual situation turned out to be different. From no age difference to a difference of nineteen years, the less the age difference, the less the *mahr* specified. Clearly, the perceived liability steadily increased as the difference in age between a younger bride and an older groom became greater. But at a difference of more than nineteen years the level of *mahr* decreased significantly and then leveled off. Seeking an explanation for this phenomenon, we realized that most of these matches were what the Druse term "nurse-bride" marriages. In these unions an older man, often a widower, takes a younger bride to help cook, manage the household, and care for any infirmities he may have. A lower *mahr* is set because the wife can expect a reasonable inheritance upon the death of her aged spouse and may also anticipate marrying again. In those rare marriages in which an older woman took a younger husband, there was no clear pattern.

Because we had data covering a 44-year period, we were also able to assess the effect that tremendous economic and social changes have had upon Druse marriage patterns. Reflecting the great economic growth of Lebanon since the early 1930s, the typical *mahr* has increased sharply. During the 1930s, the average *mahr* was 220 LL (Lebanese pounds). In the early 1970s, it was 11,461 LL, an increase of more than 5,200 percent. In other respects, however, Druse marriage patterns have changed very little. Marriages between families of different social strata (sheiks and commoners) continued to be unusual, making up less than 2 percent of the total. Unions between those belonging to different political factions are more common, but the proportion—about one in four marriages—has changed little since the 1930s. Similarly, about

Why THE AUDUBON SOCIETY ENCYCLOPEDIA is hailed as

"The bird-lover's bible!"*

IT'S HUGE, unprecedented, gloriously illustrated—the first one-volume encyclopedia to provide full, concise, impeccable information on *all* the birds that nest or have been sighted in North America.

- 1,135 pages (a million words)
- 1,675 pictures (including 875 full-color photographs)
- Nearly 6,000 alphabetical entries and cross-references, including:
- 625 major articles on all aspects of bird life
- "Biographies" of 847 birds in 78 families—appearance, habitat, range, songs, nests, behavior, and more
- Lives of 126 relevant naturalists and explorers
- 770 ornithological terms defined
- A 4,000-item bibliography

Naturalists acclaim it

ROGER TORY PETERSON says, "I intend to keep my copy near my desk, for frequent use. It is a much-needed, broad-ranging accomplishment, and a most felicitous layman's reference."

DEAN AMADON, Lamont Curator Emeritus of Birds, American Museum of Natural History: "A massive achievement...I consider it to be one of the outstanding ornithological publications of this or any other time." —From his Foreword

Reviewers extol it

"I fell in love with it!" says *Newsweek*'s critic Walter Clemons. "A monumental work that happens to be irresistibly readable."

"The most impressive American bird book since John J. Audubon's *Birds of America*," says the Associated Press..."A must for serious bird students" *(Chicago Tribune)*.

***"Destined to retain its primacy for years to come,"** says John Barkham, calling it "the bird-lover's bible!"

About the author

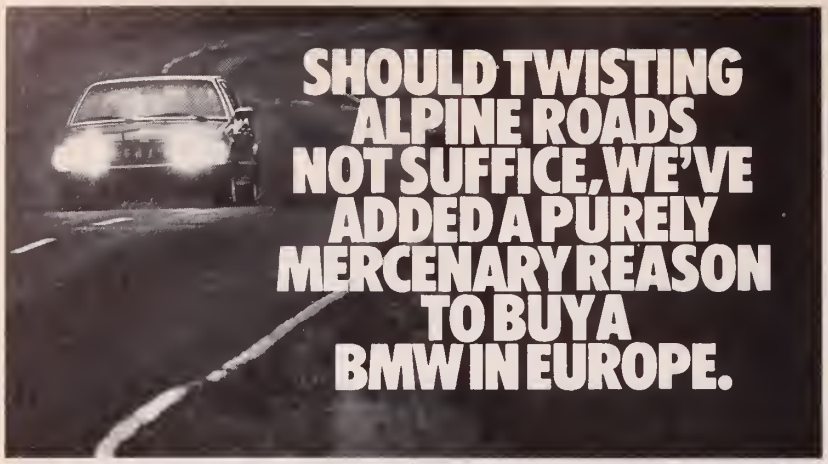
JOHN K. TERRES, who for 13 years edited *Audubon* magazine and in 1971 received the John Burroughs Medal for distinguished nature writing, has devoted over two decades to the preparation of this book.

"Awesome," writes Edmund Fuller in the *Wall Street Journal*, "is the only word for the author's knowledge of his field...A magnificent project...the extraordinary capstone of a career."

An essential reference

"This massive work," says the *Library Journal*, "is an essential reference for all libraries serving professional or amateur ornithologists."

...and a joy to have at home



"Dazzling in its beauty and abundant in its scientific treasures," says the *Christian Science Monitor*. "Captivatingly readable...If you're not the type to sit up nights perusing dictionaries and encyclopedias, this book could very well change your reading habits."

For layman and expert

When you see it at your bookseller's, you'll want it for yourself—whether you're a dedicated life-lister, a casual nature-lover, or a naturalist.

The entrancing color photographs, the detailed drawings, the wealth of content and clarity of presentation combine to make *The Audubon Society Encyclopedia of North American Birds* a necessity—and an abiding joy—for everyone interested in birds.

9 x 11 • With 1,675 illustrations in color and black-and-white
1,135 pages • $60 at all bookstores • Published by Knopf

While the thrill of mastering a spiny Alpine road in the BMW built for it remains as potent as ever, we recognize that these are value-conscious times.

We are therefore pleased to announce that a BMW bought in Europe is now substantially less expensive than one bought in the United States.

Further, if you imagine that the joys of European Tourist Delivery are clouded by 42-page forms, rest assured. Because your BMW dealer here at home handles everything.

one-third of all marriages continue to occur within a single clan, a stable proportion. Surprisingly, and in contrast to so many other groups in the modernizing societies of the Middle East, even the Druse age at first marriage has remained fairly constant during the last four decades, averaging about twenty-one for brides and twenty-eight for grooms. In spite of the many changes that have taken place in Lebanon during the last few decades, the basic structural features of Druse society have remained amazingly resilient and express little change. During the same period the frequency of divorce also remained low, affecting an estimated less than one in ten couples.

Initially, the use of the marriage contract among the Druse would appear to be much different from that envisioned by its proponents in the West. In the Middle East, it is a long-established safeguard for women, who occupy an unquestionably inferior position in relation to their husbands. It establishes a penalty the husband must pay should he divorce his wife and helps perpetuate the marriage in spite of the wife's subservient position. It also at least partly compensates widows for the economic and personal loss incurred by the death of a spouse. On the other hand, advocates of the use of the contract in the West see it as an innovation to help couples overcome the traditional subordination of women within a marriage relationship by achieving an acceptable consensus about important individual concerns.

A closer look reveals, however, that both approaches actually seek the same end—the cultivation between men and women of enduring, emotionally satisfying relationships that create a buffer against life's stresses. That a mechanism like the marriage contract has emerged from two very different cultures suggests that it may indeed be a useful tool. In our society, where the persistent quest for "something better" often results in personal relationships that are numerous, brief, and unsatisfying, no workable alternative should be overlooked.

A Most Chilling Statement

A Russian scientist's name has been rehabilitated, and his ideas are resurfacing, too

by Stephen Jay Gould

In 1936, Trofim D. Lysenko, struggling to reform Russian agricultural science on discredited Lamarckian principles, wrote: "I am not fond of controversy in matters concerning theory. I am an ardent controversialist only when I see that in order to carry out certain practical tasks I must remove the obstacles that stand in the way of my scientific activities."

As his practical task, Lysenko set out to "alter the nature of plants in the direction we desire by suitable training." He argued that previous failure to produce rapid and heritable improvements in important crop plants must be laid to the bankrupt ideology of bourgeois science, with its emphasis on sterile academic theory and its belief in Mendelian genes, which do not respond directly to the prodding of breeders but change only by accidental and random mutation. The criterion of a more adequate science must be success in improved breeding.

"The better we understand the laws of development of plant and animal forms," he wrote, "the more easily and quickly will we be able to create the forms we need in accordance with our wishes and plans." What "laws of development" could be more promising than the Lamarckian claim that altered environments can directly induce heritable changes in desired directions? If only Nature worked this way! But she does not, and all Lysenko's falsified data and vicious polemics budged her not one inch.

If Lysenko's "obstacles" had been disembodied ideas alone, the history of Russian genetics might have been spared some of its particular tragedy. But ideas emanate from people, and the obstacles designated for removal were necessarily human. Nikolai Ivanovich Vavilov, Russia's leading Mendelian geneticist and director of the All-Union Lenin Academy of Agricultural Sciences centered in Leningrad, served as a focal point for Lysenko's attacks in 1936. Lysenko castigated Vavilov for his general Mendelian views, but any geneticist might have served equally well for such generalized target practice. Lysenko singled out Vavilov for a more specific and personal theory (and the subject of this column)—the so-called law of homologous series in variation.

Twelve years later, following the devastation of war, Lysenko had triumphed. His infamous address, "The Situation in Biological Science," read at the 1948 session of the Lenin Academy of Agricultural Sciences, contains as the first statement of its summary what may well be the most chilling passage in all the literature of twentieth-century science.

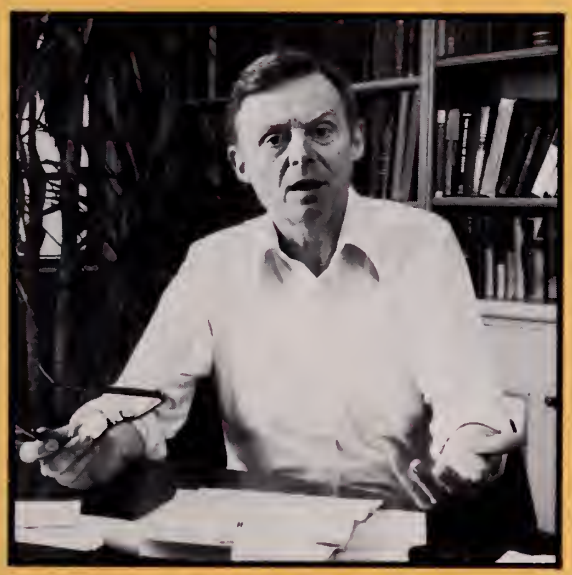
> The question is asked in one of the notes handed to me, "What is the attitude of the Central Committee of the Party to my report?" I answer: The Central Committee of the Party has examined my report and approved it [*Stormy applause. Ovation. All rise*].

Following another ten pages of rhetoric and invective, Lysenko concludes: "Glory to the great friend and protagonist of science, our leader and teacher, Comrade Stalin! [*All rise. Prolonged applause.*]"

Nikolai Vavilov was unable to attend the 1948 meeting. He had been arrested in August 1940 while on a collecting expedition in the Ukraine. In July 1941, he was sentenced to death for agricultural sabotage, spying for England, maintaining links with émigrés, and belonging to a rightist organization. The sentence was commuted to ten years imprisonment, and Vavilov was moved to the inner prison of the NKVD in Moscow. In October, he was evacuated to the Saratov prison where he spent several months in an underground death cell, suffering from malnutrition. He died, still a prisoner, in January 1943.

What is Vavilov's "law of homologous series in variation," and how did it provide Lysenko with rhetorical leverage? Vavilov published this law, the guiding principle for much of his practical work in agricultural genetics, in 1920 and revised it in 1935. It was printed in English in the prestigious *Journal of Genetics* in 1922 (vol. 12, pp. 48–89).

Vavilov was perhaps the world's leading expert on the biogeography of wheat and other cereals. He traveled throughout the world (thereby leaving himself vulnerable to trumped-up charges of espionage), collecting varieties of plants from their natural habitats and establishing the world's largest "bank" of genetic variation within major agricultural species. As he collected natural races of wheat, barley, oats, and millet over a large range of environments and places, he noticed that strikingly similar series of varieties could be found within the different species of a genus and often within species of related genera as well.



He collected, for example, a large number of geographical races within the species of common wheat, *Triticum vulgare*. These varied in complex sets of traits, including color of the ears and seeds, form of the ears (bearded or beardless, smooth or hairy), and season of maturation. Vavilov was then surprised and delighted to find virtually the same combinations of characters in varieties of two closely related species, *T. compactum* and *T. spelta*.

He then studied rye (*Secale cereale*), a species in a genus closely related to wheat but previously regarded as much more limited in its geographical variation. Yet, as Vavilov and his assistants collected rye throughout European and Asiatic Russia, Iran, and Afghanistan, he found not only that its differentiation matched wheat in extent but also that its races displayed the same sets of characters, with the same variations in color, form, and timing of growth.

The similarities in series of races were so precise and complete between related species that Vavilov felt he

Some people say...

"I moved from the suburbs to the city and my auto insurance rates went up. What's going on?"

That's why we want you to know...

People who live in cities usually pay higher auto insurance premiums than people who live in suburban or rural areas.

Why? Because car owners in large urban areas face greater exposure to loss. The concentration of people and autos inevitably results in more accidents. (Traffic experts call it "friction of the system.")

Theft and vandalism occur more frequently. And the costs of hospital and medical care, car repairs, lost wages, and lawsuits—all the things insurance pays for—are generally higher in urban areas.

Insurance companies want rates to be as fair as possible. Experience tells us the best way to do this is to charge policyholders higher or lower premiums according to their exposure to loss.

So, in making auto insurance rates, insurance companies consider the differences in costs by "territories" as an important factor.

We sympathize with those drivers whose place of residence puts them in higher rate categories. But if "territories" were eliminated, people who live in less congested areas and who, therefore, have less exposure to loss would end up subsidizing people who live in large urban areas and who have far greater exposure to loss.

And we don't think that's fair.

We're working to keep insurance affordable.

This message presented by the **American Insurance Association,** 85 John Street, NY, NY 10038

could predict the existence of undiscovered varieties within one species after finding their parallel forms in another species. In 1916, for example, he found several varieties of wheat without ligules in Afghanistan (ligules are thin membranes that grow from the base of the leaf blade and surround the stem in many grasses). This discovery suggested that varieties of rye without ligules should also exist, and he grew them from seeds collected in Pamir in 1918. He predicted that durum wheat (*Triticum durum*), then represented exclusively by spring varieties, should also have winter forms since related species do—and he found them in 1918 in an isolated region of northern Iran.

Vavilov's observation would have engendered less controversy had he not interpreted it, indeed overinterpreted it, in a manner uncongenial with strictly Darwinian or Lamarckian views. He might have argued that his series of parallel varieties represented similar adaptations of different genetic systems to common environments that engendered natural selection in the same direction. Such an interpretation would have satisfied Darwinian preferences for random variation, with evolutionary change imposed by natural selection. (It could also have been distorted by Lysenko into a claim that environments directly altered the heredity of plants in favorable ways.)

But Vavilov proposed a different explanation more in tune with non-Darwinian (though not anti-Darwinian) themes still popular during the 1920s: he claimed that the parallel series of varieties represented identical responses of the same genetic systems, inherited in toto from species to related species. Thus, in evolutionary parlance, his series were "homologous"—hence the name of his law. (Homologies are similarities based on inheritance of the same genes or structures from a common ancestor. Similarities forged within different genetic systems by selective pressures of similar environments are called analogies.)

Vavilov argued that new species arise by developing genetic differences that preclude interbreeding with related species. But the new species is not genetically distinct from its ancestor in all ways. Most of the ancestor's genetic system remains intact; only a limited number of genes are altered. The parallel varieties, then, represent a "playing out" of the same genetic capacities inherited as blocks from species to related species.

Such an interpretation is not anti-Darwinian because it does not deny an important role to natural selection. While each variety may represent a predictable latent capacity, its expression in any climate or geographical region still requires selection to preserve the adaptive variant and to eliminate others. But such an explanation does conflict with the spirit of strict Darwinism because it weakens or compromises the cardinal tenet that selection is *the* creative force in evolution. Random, or undirected, variation plays a crucial role in the Darwinian system because it establishes the centrality of selection by guaranteeing that evolutionary *change* cannot be ascribed to variation itself. Variation is only raw material. It arises in all directions or, at least, is not preferentially ordered in adaptive ways. Hence, direction is imposed by natural selection, slowly preserving and accumulating, generation after generation, the variations that render organisms better adapted to local environments.

But what if variation is not fortuitous and undirected but strongly channeled along certain paths. Then only a limited number of changes are possible, and they record the "internal" constraints of inheritance as much as the action of selection. Selection is not dormant; it still determines which of several possibilities reaches expression in any one climate or area. But if possibilities are strictly limited, and if a species displays all of them among its several varieties, then this range of form cannot be ascribed only to selection acting upon fortuitous variation.

Moreover, this explanation for new varieties undermines the cardinal principle of creativity for natural selection. The variations are predictable results within their genetic system. Their occurrence is almost foreordained. The role of natural selection is negative. It is an executioner only. It eliminates the variants unfit in any given environment, thus preserving the favored form that had to arise eventually.

Vavilov interpreted his law of homologous series in this non-Darwinian manner. "Variation," he wrote, "does not take place in all directions, by chance and without order, but in distinct systems and classes analogous to those of crystallography and chemistry. The same great divisions [of organisms] into orders and classes manifest regularities and repetitions of systems." He cites the case of "several varieties of vetches so similar to ordinary lentils in the shape, color, and size of their seeds, that they cannot be separated by any sorting machine." He agrees that the extreme similarity in any one spot is a product of selection—unconscious selection in agricultural sorting machines. But the agent of selection was, literally in this case, only a sieve that preserved one variant among many. The proper variant existed already as a realized product of an inherited set of possibilities.

The role of natural selection in this case is quite clear. Man unconsciously, year after year, by his sorting machines separated varieties of vetches similar to lentils in size and form of seeds, and ripening simultaneously with lentils. The same varieties certainly existed long before selection itself, and the appearance of their series, irrespective of any selection, was in accordance with the laws of variation.

Vavilov, overenthused with his own idea, went on. He became intoxicated with the notion that his law might represent a principle of ordering that would render biology as exact and experimental as the "hard" sciences of physics and chemistry. Perhaps genetic systems are composed of "elements." Perhaps the geographical varieties of species are predictable "compounds" that arise inevitably from the union of these elements in specified mixtures. If so, the ranges of biological form within a species might be laid out in a table of possibilities similar to the periodic table of chemical elements. Evolution might be deduced from genetic structure itself; environment can only act to preserve inherent possibilities.

He advocated an explicit "analogy with chemistry" in the concluding section of his 1922 paper and wrote: "New forms have to fill vacancies in a system." He experimented with a style of notation that expressed varieties of a species as a chemical formula and advocated "the analogy of homological series of plants and animals with systems and classes of crystallography with definite chemical structures." One zealous supporter commented that "biology has found its Mendeleev."

Vavilov moderated his views during the 1920s and early 1930s. He learned that some of the parallel varieties between species are not based upon the same genes after all, but represent

Why a Hasselblad costs more than other cameras.

It takes a full year to make a Hasselblad camera. Almost every part right down to the smallest screw, is made by Hasselblad. There is no mass production involved. All the parts are assembled by hand, and fit together with extraordinary precision.

A Hasselblad is designed and constructed to give long years of optimum performance to the professional photographer, who depends on his camera for his livelihood. Consequently, a Hasselblad camera is both rugged and sensitive—an exquisitely responsive photographic instrument of the sturdiest construction.

Because a Hasselblad gives performance far beyond that of other cameras, the Hasselblad design philosophy centers around "continuity"

rather than "obsolescence". New accessories will fit Hasselblad cameras of 20 years ago.

In the long run, a Hasselblad not only pays for itself by its performance, but also retains its value. In fact, Hasselblad cameras have been sold, after years of usage, for more than twice the original purchase price.

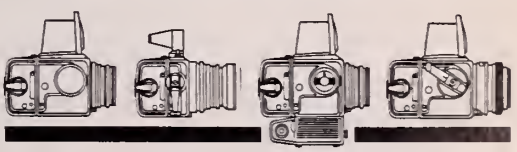
Hasselblad is founded on the principle of interchangeability of parts, so once you own a Hasselblad camera, you have access to the entire Hasselblad System—the most comprehensive of its kind.

There are four camera models to choose from.

First, there is the Hasselblad 500 C/M, with leaf shutter and flash synch speeds up to 1/500 second.

A more specialized camera is the Hasselblad Superwide C/M, with a built-in wide angle lens that gives a distortion-free 90° angle of view.

The 500 EL/M motor Hasselblad, ideally suited for fast shooting and remote control operation.



And then, the superb Hasselblad 2000 FC, with an electronically-controlled shutter that provides speeds up to 1/2000 second.

As your needs grow, you can modify your Hasselblad accordingly by interchanging the lenses, viewfinders and film backs, as well as utilizing any of the numerous accessories.

You can even change film formats—something you can't do with other cameras. For example, you can shoot in the truly ideal 2¼" square format that makes it easy to view, frame and focus, and that results in an image 3½ times larger than 35mm. Or simply snap off the film magazine back and instantly replace it with a 6 x 4.5 cm format magazine, which enlarges to 8" x 10". Your third choice is to shoot "superslides" that project on any 35mm projector, but give you twice the image area of 35 mm, dramatically filling the screen.

So, while a Hasselblad costs more, it's easy to see why so many serious photographers feel they can't afford to be without it.

See your Hasselblad franchised dealer or write for one of our bulletins on square composition, and a comprehensive brochure on the Hasselblad system to: Victor Hasselblad Inc., Dept. A-14, 10 Madison Road, Fairfield, N.J. 07006.

the similar action of selection upon different sources of variation. In these cases, the varieties are analogous, not homologous, and the Darwinian explanation must be preferred. He wrote in 1937:

> We underestimated the variability of the genes themselves. . . . At the time we thought that the genes possessed by close species were identical; now we know that this is far from the case, that even very closely related species which have externally similar traits are characterized by many different genes. By concentrating our attention on the variability itself, we gave insufficient attention to the role of selection.

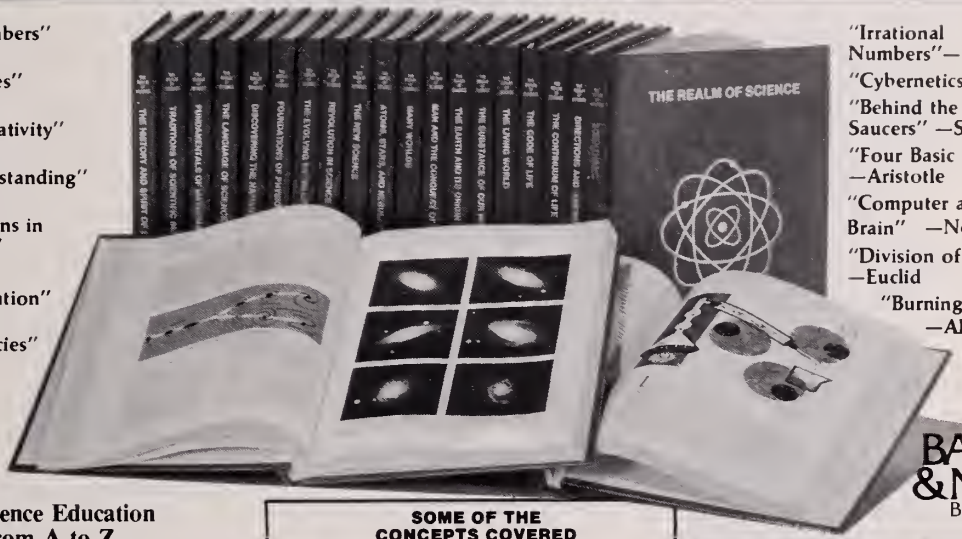
Still, Vavilov continued to champion the importance and validity of his law, and he continued to advocate the analogy with chemistry in only slightly weakened form.

Unfortunately, in the deepest sense, Vavilov had left himself open to Lysenko's polemical attack. The law of homologous series provided Lysenko with important ammunition, and Vavilov's overextended chemical analogy deepened his troubles. Lysenko caricatured Vavilov's law in 1936 by presenting ridiculous examples involving species too distantly related to present parallel series in Vavilov's system: "In nature we find apple trees with round fruit, hence there must or can be trees with round pears, cherries, grapes, etc."

Lysenko's ideological attack was more vicious. He made two major charges involving both parts of that catchword for official Soviet philosophy—dialectical materialism. Vavilov's law, he claimed, was undialectical because it located the source of organic change within the genetic systems of organisms themselves and not in the interaction (or dialectic) between organism and environment. Secondly, Lysenko charged that the law of homologous series was "idealist" rather than materialist because it viewed the evolutionary history of a species as prefigured in the unrealized (and therefore nonmaterial) capacity of an inherited genetic system.

Evolution, Lysenko charged, is almost an illusion in Vavilov's scheme. It represents a mere playing out of inherited potentials, not the development of anything new. It expresses the bourgeois penchant for stability by depicting apparent change as a superficial expression of underlying constancy. According to Vavilov's law, Lysenko charged,

> New forms result not from the development of old forms, but from a reshuffling, a recombination of already existing hereditary corpuscles. . . . All the existing species existed in the past, only in less diverse forms; but every form was richer in potentialities, in its collection of genes.



Madness often displays a perverse but cogent reason in its own terms; and we must admit that Lysenko did identify and exploit the true weaknesses in Vavilov's argument. Vavilov did underplay the creative role of environment, and his chemical analogy did betray a belief in prefigured potentiality as the source of later, and in some sense illusory, change. But Lysenko, who was also both a charlatan and a cruel polemicist, was equally undialectical (despite his protestations to the contrary) in viewing plants as putty before a molding environment.

The Soviets killed Vavilov in the name of a phony Lamarckism. He became a legitimate martyr in the West, but his ideas did not flourish as a result. The law of homologous series, the organizing theme of his evolutionary work, was ignored in the name of an overly strict Darwinism. Vavilov's law did not directly contradict Darwinian principles, but its emphasis on constraints of inheritance and channeled variation fit poorly with the favored Darwinian theme of random variation and the guidance of evolutionary change by natural selection. It was therefore neglected and relegated to the shelf of antiquated theories that had implicated variation itself as a directing force in evolution. I have consulted all the founding documents of the "modern synthesis," the movement that established our present version of Darwinism between the late 1930s and the 1950s. Only two mention Vavilov's law of homologous series, each in less than one paragraph.

Yet I feel that in his imperfect way Vavilov had glimpsed something important. In more modern terms, new species do not inherit an adult form from their ancestors. They receive a complex genetic system and a set of developmental pathways for translating genetic products through embryology and later growth into adult organisms. These pathways do constrain the expression of genetic variation; they do channel it along certain lines. Natural selection may choose any spot along the line, but it may not be able to move a species off the line—for selection can only act upon the vari-

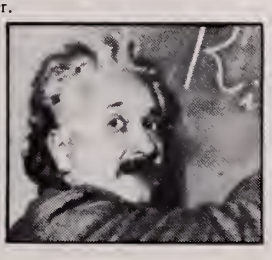
A Science Education from A to Z



From the *ABC of Relativity* by Bertrand Russell, to Zeno's paradoxes, this 21-volume library provides a complete and fascinating science education.

Unlike an encyclopedia, this reference work is one you can read for pure enjoyment as well as refer to for reliable information. The key to this readability is the fact that THE REALM OF SCIENCE is actually a massive collection of selected writings arranged and indexed by subject. It is so complete, that the cumulative index alone runs almost 200 pages!

Think of a subject, look it up, and read what the world's foremost authorities have written about it.

The Greatest Minds the World Has to Offer

The authorities represented in this priceless collection read like a "Who's Who" in science. There's Priestley on the discovery of oxygen; Faraday on electrochemistry; E.O. Wilson on sociobiology; Ernst Nagel on Godel's proof. Plus Isaac Asimov, Jacob Bronowski, Martin Gardner, Max Planck, James Watson, George Gamow, Fritz Zwicky, and hundreds more. From ancient Babylonia to the present, you will be exposed to the greatest minds the world has to offer.

Einstein's special theory of relativity changed our concept of time, distance and mass.

A Valuable Research Tool

Although each volume contains its own index, the unique Science Concept Index "brings it all together." It will help you find vital information on a given subject, person, place or idea throughout the set. It will also enable you to trace various applications of a subject from one author to another, from one concept to another, or from one discipline to another. Imagine what a valuable research tool this can be. Taken as a whole, this 21-volume set provides an overview of science never before possible in a single work.

SOME OF THE CONCEPTS COVERED

- —Air
- —Astronomy
- —Atoms
- —Axioms-Laws-Principles
- —Behavior
- —Biology
- —Cells
- —Chemistry
- —Communication
- —Computers
- —Conservation
- —Continuity
- —Cosmology
- —Desert

Small Ad for a Big Tour of the Orient

Japan Air Lines has 35 very special tours to the Orient. Come, let us take you to the Orient of your dreams.
Here is but one example:
Mandarin Orient, 19–24 days, $3197–3675. All tours visit Hong Kong, Peking, Shanghai and Canton. Some tours also visit Tokyo, Penang, Singapore, Bangkok as well as certain cities in China. All tours fully escorted and most meals are included.

Rates based on double occupancy and economy air fare from the West Coast and are subject to change. Additional charge for June–October peak season.

SPEND A WEEK AT CORNELL!
1981 SEMINARS IN ORNITHOLOGY
CORNELL LABORATORY OF ORNITHOLOGY
now is offering summer seminars in ornithology in addition to its popular Home Study Course in bird biology.

Our summer courses are designed to extend and complement the Home Study Course with personalized instruction and laboratory and field exercises. You will have an opportunity to select one or more of three one-week, non-credit summer seminars in bird biology. The courses are taught at the Laboratory of Ornithology and are offered at three levels: beginning, intermediate, and advanced. Topics covered include methods of field identification by sight and sound, avian ecology, anatomy and physiology, and much more. The tuition fee includes room and board. Enrollment in the summer courses is limited, so don't delay. Write now for further information.

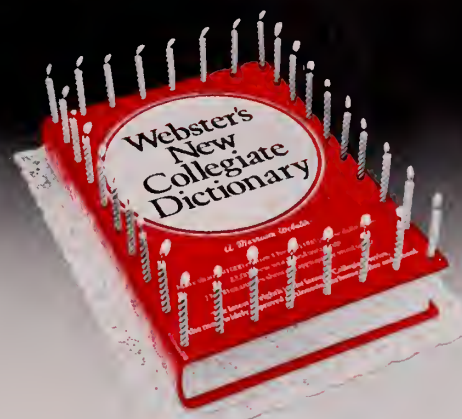
For more information about our Home Study Course and our 1981 Summer Seminars in Ornithology write:
Dept. NH, 159 Sapsucker Woods Road, Ithaca, NY 14850.

ation presented to it. In this sense, constraints of variation may direct the paths of evolutionary change as much as selection acting in its Darwinian role as a creative force.

I have found Vavilov's views very helpful in reorienting my own thinking in directions I regard as more fruitful than my previous unquestioned conviction that selection manufactures almost every evolutionary change. In studying the relationship of brain size to body size, biologists find that brains increase only one-fifth to two-fifths as fast as bodies in comparisons of closely related mammals differing only (or primarily) in body size—adults within a single species, breeds of domestic dogs, chimpanzees versus gorillas, for example. For ninety years, the large literature has centered on speculations about the adaptive reasons for this relationship, based upon the (usually hidden) assumption that it must arise as the direct product of natural selection.

But my colleague Russell Lande recently called my attention to several experiments on mice selected over several generations for larger body size alone. As these mice increased in size across generations, their brains enlarged at the characteristic rate—a bit more than one-fifth as fast as body size. Since we know that these experiments included no selection upon brain size, the one-fifth rate must be a nonadaptive side product of selected increase in body size alone. Since the one-fifth to two-fifths rate appears again and again in diverse lineages of mammals, and since it may record a nonadaptive response of brains to selection for larger bodies within mammalian developmental systems, the parallel sets of races and species arrayed along the one-fifth to two-fifths slope in carnivores, rodents, ungulates, and primates are non-Darwinian homologous series in Vavilov's sense.

In personal research on the West Indian land snail *Cerion*, my colleague David Woodruff and I find the same two morphologies again and again in all the northern islands of the Bahamas. Ribby, white or solid-colored, thick, and roughly rectangular shells inhabit rocky coasts at the edges of banks where islands drop abruptly into deep seas. Smooth, mottled, thinner, and barrel-shaped shells inhabit calmer and lower coasts at the interior edges of banks, where islands cede to miles of shallow water. The easiest,



and usual, conclusion would view ribby shells on all islands as closely related and smooth shells as members of another coherent group. But we believe that the complex set of characters forming the ribby and smooth morphologies arise independently, again and again. On the islands of Little Bahama Bank, both ribby and smooth animals share a distinctive genital anatomy. On the islands of Great Bahama Bank, both ribby and smooth develop an equally distinctive, but different, kind of penis. The ecology of rocky versus calm coasts may select for ribby and smooth morphologies as adaptations, but the coordinated appearance of the half dozen distinctive traits of each morphology, again and again, may represent a channeling of available variation to produce homologous series (ribby and smooth varieties) in different lineages (defined by genital anatomy).

A complete theory of evolution must acknowledge a balance between "external" forces of environment imposing selection for local adaptation and "internal" forces representing constraints of inheritance and development. Vavilov placed too much emphasis on internal constraints and downgraded the power of selection. But Western Darwinians have erred equally in practically ignoring (while acknowledging in theory) the limits placed upon selection by structure and development—what Vavilov and the older biologists would have called "laws of form." We need, in short, a real dialectic between the external and internal factors of evolution.

Vavilov's personal tragedy cannot be undone. But he has been rehabilitated in Russia, where the All-Union Society of Geneticists and Selectionists now bears his name. We who view him as a martyr and champion his name while ignoring his ideas would do well to reconsider the older non-Darwinian tradition that he represented. Combined with our legitimate conviction about the power of selection, the principle of homologous series (and other "laws of form") might foster an evolutionary theory truly synthetic in its integration of development and organic form with a body of principles now dominated by ecology and the effects of selection upon single genes and traits.

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

UNUSUAL.

That's the ideal description of the regal island country of Sri Lanka, once known as Ceylon. It's a fabulous spectacle. Whether you're looking at our ancient cities, wondrous wildlife or miles of beaches. The ultimate is our festival of the August moon. Located in the Jasmine-scented, mountain city of Kandy, you will feast your eyes on a thousand whirling dancers, a hundred costumed elephants, and more drummers than you've ever seen. The torchlight acrobatics of this 2,000 year old Perahera will, in just a few days, leave you with a lifetime of memories.

We have an unusual variety of tours – 75 in all – ranging from 3 to 21 days. The prices? Unusually low! Accomodations begin at $5. Deluxe sells for $45.

Sri Lanka is a most unusual warm weather vacation or convention spot. Only one hour from India, three hours from Katmandu, Bangkok and Singapore. Write for a color folder and tour digest that includes special airfare.

Disturbing Plants

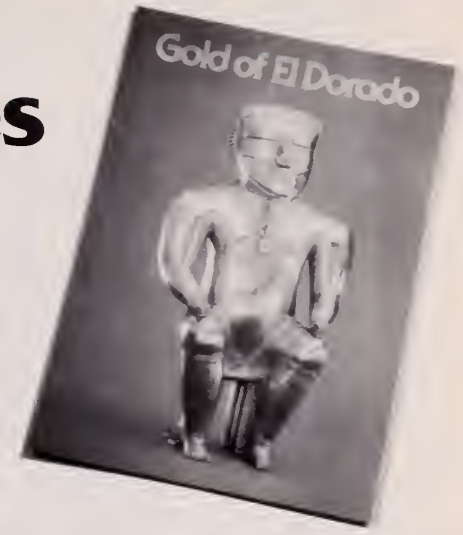
Violence is a natural part of all plant communities; a disturbance that devastates one species may create opportunities for another

by Robert E. Cook

The English painter J. M. W. Turner certainly captured the sublime, violent power of nature in his art. In 1810 he exhibited a landscape, *Cottage Destroyed by an Avalanche,* accompanied by the following lines:

The downward sun a parting
sadness gleams
Portentous lurid thro' the
gathering storm;
Thick drifting snow, on snow,
Till the vast weight burst
thro' the Rocky barrier;
Down at once, its pine clad forests,
and towering glaciers fall,
the work of ages
Crashing through all! extinction follows
And the toil, the hope of
man—o'erwhelms.

Surging diagonally across the canvas, a rush of rock and white ice carry massive boulders down an Alpine slope against a wild, darkening sky. Along the base of the painting, small, spiky conifers accentuate the vast scale of the devastation. Amidst these trees, a wooden cottage is splintering beneath the debris. Turner's vision of a capricious, catastrophic nature strongly suggests a revolutionary reaction against the classical tradition of stability in landscape. In the classical style, so characteristic of the European painters Claude Lorrain and Nicolas Poussin, the quiet, pastoral countryside is drawn with strong vertical and horizontal lines of stately foliage and massive architecture, perpetuating a sense of order and permanence in nature.



One might expect to find such strikingly different interpretations of landscape only among artists. Plant ecologists, however, are currently in the midst of a similar revolutionary revision of deeply held convictions concerning natural vegetation. In particular, old notions about the stability of the American wilderness before the European settlers arrived have been severely shaken by reconstructions of vegetational history. Before discussing these new views, however, I should sketch the origins of our traditional wisdom.

The Moses of American plant ecology is Frederick E. Clements, who, at about the turn of the century, was the first naturalist to frame a comprehensive and intricate theory of plant communities. Because he studied the dynamics of vegetation and not the flora of a region, Clements considered himself an ecologist rather than a plant taxonomist, who identifies the species composition of plant communities. The study of vegetation is concerned with the behavior of the plant ensembles in a habitat, their biomass, relative abundances, and structural relations. More than a listing of species, this approach tries to relate these characteristics of the whole community to aspects of the physical environment, such as precipitation, soil conditions, and growing season.

Clements believed that the vegetation in a region is a living entity, a superorganism, capable of progressive development, stable maturity, and reproduction. During this period in the history of biology, organismic metaphors were most attractive to scientists. Clements gave the name climax plant community to what he considered the adult form of vegetation in a region, the primeval virgin landscape that existed before the coming of settlers with ax and plow. Climax communities, which in Clements's view represented the highest development of vegetation, once covered vast tracts of continental land and were dominated in each region by a few characteristic species determined by climate. In New England, for instance, the classical climax forest (which stretched, unbroken, from Nova Scotia to Wisconsin) was a mixture of ancient beeches, hemlocks, and sugar maples.

Arrayed against these vegetational entities, Clements saw the forces of destruction: tornadoes, landslides, fires, and humans. To cope with these assaults, he argued, vegetation has evolved a mechanism of self-replication, or repair, called succession. After a patch of vegetation is devastated,

An Art Book That Took Centuries To Create

It took the American Museum of Natural History four years to arrange its exceptional exhibition of more than 500 pieces of ancient gold from Colombia. But those few years are a brief time when compared with the decades archeologists have spent digging (literally!) and studying the gold artifacts from tombs, caves, and buried sites. And all that time is short when compared with the many centuries prehistoric Indians practiced their craftsmanship and artistry to create these treasures.

So when it became the United States sponsor for this outstanding collection, the American Museum faced a dilemma. Could we do justice to all this effort and scholarship and beauty? We think we have. First, by dramatically displaying *Gold of El Dorado: The Heritage of Colombia* in one of our largest halls. The glowing reports from visitors tell us our efforts have been worthwhile. If you don't have a chance to see the show for yourself in New York, we hope you will see it in Chicago, San Francisco, or New Orleans on its year and a half tour.

The second challenge for the American Museum was the creation of an appropriate book to accompany the exhibition. We decided against a traditional catalog; against a small, boring volume with tiny black-and-white pictures that could never do justice to these fine objects. Instead, we decided to present a select number of the finest pieces of pre-Columbian gold in a large, stunning format. And to represent the three important elements that make a great art book we chose outstanding professionals.

First, photographer Lee Boltin. One of the greatest photographers of art objects, he also took the famous pictures of the Tutankhamun show. We sent him abroad to find and record great pieces of pre-Columbian art.

Second, archeologist Warwick Bray, from the University of London. One of the world's foremost authorities on pre-Columbian art, Bray is also a skilled writer, able to present fascinating background in a succinct, readable essay in the book. Dr. Bray organized the Colombian gold exhibition in London.

Third, Harry N. Abrams, Inc., America's leading publisher of fine art books. In a co-publishing venture with the American Museum, Abrams designed the book, supervised the preparation of 30 large color plates, and monitored the fine-quality printing.

The result is an unprecedented exhibition book. It is bold and big—each plate is 16 by 11½ inches—bigger than this magazine *opened up*. The paper is heavier than most posters. In fact, many persons have purchased two copies of the book in order to have one set of these fine art prints for framing.

And now for the happy ending. Because the Museum is a co-publisher, we are able to offer this soft-bound art book at a major savings from its normal retail price of $12.50. We are pleased to offer *Gold of El Dorado* to subscribers for only $6.25—a 50% savings off its regular price. This special offer is valid only during the exhibition and only while our limited supply lasts. We suggest that you order one or more copies immediately. Of course, if you are not satisfied after you have had an opportunity to examine it in your home, simply return the book and the Museum will refund the purchase price.

the denuded site is colonized by a sequence of species that gradually alters the habitat in ways favoring a return to the structure and content of the original climax composition. Clements viewed the successional changes initiated by external disturbance as part of a progressive, internally controlled process of development, analogous to the transformations in the ontogeny of an organism. The natural state of vegetation, then, is mature climax: permanent and perpetually stable, although marred occasionally by transient patches of successional plant communities, the kinds of herbs and shrubs that colonize abandoned farmland before the mature forest develops.

This view of disturbance as a violent force external to stable vegetation had some direct effects on wilderness-preservation policies. About the turn of the century, when large expanses of forest were set aside as public land, a major priority was the establishment of a system of fire suppression. Isolated fire guards in mountain watchtowers, highly trained platoons of firefighters, and complex systems of weather forecasting all proliferated in national parks and forests, accompanied by public exhortations proclaiming the evil of fire caused by the careless hand of man. Economic and safety considerations also shaped the policy of fire suppression, but conservationists and plant ecologists alike, wishing to preserve some virgin wilderness, accepted unquestioningly the beneficial effects of such policies on forest preservation. The destructive effects of fires set by humans were seen as a tremendous threat.

Just how frequent were catastrophic fires prior to the arrival of settlers? To answer this question, Miron Heinselman, a forest ecologist at the University of Minnesota, spent six years carefully reconstructing, back to A.D. 1595, the fire history of virgin coniferous forests in the Boundary Waters Canoe Area of northern Minnesota. By probing the historical accounts of explorers and trappers and the records of geologic surveys and the Forest Service, Heinselman was able to reconstruct a history of recurrent fire. He then mapped the distribution of forest communities, particularly noting fire-adapted species, such as jack pine, whose seedlings germinate and establish primarily after burning. Heinselman supplemented this analysis with age records of individual trees, determined by counting the annual rings in a core of wood sampled from the trunk. By analyzing the history of close to a million acres, he has identified large stretches of landscape that have experienced one or more burns and can precisely establish the time of each fire.

Since 1900, when the Forest Service began its policy of fire suppression, relatively few major burns have occurred in the Boundary Waters Canoe Area, with an average interval of twenty-six years between significant fires anywhere in the forest. During the fifty years of settlement prior to the adoption of fire-suppression policies, a serious fire destroyed some part of the forest every two years. More surprising, Heinselman discovered that fires were occurring nearly as frequently—at intervals of only four years—for the three hundred years before the first European settlements. On average, a given stand of forest will burn every hundred years, indicating that the climax condition is barely achieved before it is destroyed. Thus, the virgin spruce-fir climax was normally subject to frequent catastrophic destruction, which continually maintained some fraction of the vegetation in the process of succession.

Albert Swain, a colleague of Heinselman's, has extended this fire history an additional 1,000 years into the past by analyzing sediment cores from Lake of the Clouds, situated in the center of the virgin forest. Each year, this lake lays down a distinguishable layer of bottom mud consisting of sediments and pollen carried in from the surrounding drainage basin. By identifying charcoal bands and jack pine pollen, Swain dated the major fires in the vicinity. For any forest stand, he found the average frequency of burning was sixty to seventy years. The cores also contain charcoal deposits and a high abundance of jack pine pollen throughout the historical record.

Fire, and the consequent destruction and succession of plant communities, appears to be a recurrent and natural event in these forests. Historically, the major burnings coincide with years of summer drought and are probably ignited by lightning. In addition to maintaining species diversity, frequent fires recycle mineral nutrients tied up in plant tissue and prevent the accumulation of highly flammable brushwood and dead timber, which support massive, uncontrollable conflagrations. A policy of fire suppression could be causing permanent and unpredictable changes in the natural vegetation of wilderness areas.

Fire is not the only kind of disturbance. John Henry and Mark Swann, working at the Harvard Forest, have published an equally meticulous historical reconstruction of virgin Pisgah Forest in southwestern New Hampshire back to A.D. 1665. By coring living and dead trees and carefully dissecting soil layers for evidence of dead trees and fire, these workers found a recurrent pattern of violent disturbance that prevented any orderly succession. In 1665, the vegetation was completely destroyed by a catastrophic fire, which the authors speculate may have been fueled by the many dead, dry trees blown down by a hurricane that passed through the area in 1635. During the following 270 years, three violent windstorms, in 1898, 1909, and 1921, interrupted the development of a forest of hemlock and white pine and brought down nearly half the trees. Finally, the Great Hurricane of 1938 swept through central New England and destroyed the entire forest, leaving a crisscross lattice of uprooted trunks. Today these ghosts of former trees, each with a jagged web of roots radiating from its base, lie in decay beneath layers of moss and fallen litter. In the wake of the hurricane's destruction, a new forest completely different in composition began to develop from saplings that had survived the winds and from seedlings able to germinate and grow in the open pits of raw soil. Henry and Swann found little evidence for any process of orderly succession and concluded that the composition of the forest was largely determined by the history of disturbance.

The behavior of each species in Pisgah Forest is illuminating. White pine seedlings, for instance, colonized the ash layer only after the severe fire of 1665 and only until 1687. Hemlock also invaded after the 1665 burning but continued to establish plants until 1780. No new hemlock seedlings appeared until the windstorms about the beginning of the twentieth century. Black birch and red maple were absent from the forest until the major tree blowdowns of 1921 and 1938. Black birch appears particularly adapted to the raw soil clinging to the upturned roots of trees, while red maple prefers the damper pits of accumulating litter beneath. The establishment of these

A collection of limited edition bird engravings . . . try the first one in your home free for 15 days

Songbirds of the World

ENGRAVINGS

Beautify your home with these original color engravings.

Each one matted in silk and framed for immediate display.

And available to you at the very attractive price of just $29 each.

THE BALTIMORE ORIOLE. Framed engraving shown smaller than actual size of 11¾" x 8¾"

When a renowned nature artist and a master engraver combine their talents, the result is sheer magic! And there is magic in the original color engravings that comprise this unique collection. Eight of the world's most beautiful and delightful songbirds are interpreted in art by the famed ornithological artist Robin Hill and the distinguished engraver Yves Beaujard.

Created in the tradition of John James Audubon, these new color engravings are not only works of art—they are also a lovely enhancement for your home. And you will be able to display each one the moment it arrives—because it will be sent to you *matted in silk and framed*. Moreover, you can examine the first engraving—*The Baltimore Oriole*—free for 15 days.

Realistic art—masterful engraving

A perfectionist in every sense, Robin Hill produced dozens of sketches of each bird from every angle. Next he refined his sketches, over and over again, before creating the final art. Hill has meticulously portrayed every detail, every feature of the birds—and has paid careful attention to re-creating their magnificent colors. The brilliant black and orange of *The Baltimore Oriole*, the rich blue of *The Indigo Bunting*, the marvelous tones of *The European Goldfinch*, *The Rufous Whistler*, *The Linnet*, *The Long-tailed Rosefinch*, *The Multicolored Tanager* and *The Diamond Firetail*.

Engraver Yves Beaujard then took the artist's original works and *hand-engraved* the master plate for each—making sure to capture every element and every subtle nuance of the artist's work.

This method of working—the artist and engraver together—is all but a lost art in our day. Yet the result is well worth the effort. For the final engravings are works of stunning beauty. And they are unusual—because hand-engraving adds a crispness of line and detail that other art forms rarely achieve.

A limited edition at an uncommon price

"Songbirds of the World" will be issued in limited edition—available *only* during this year. After that, the collection will never be produced again. Furthermore, it can be acquired *only* from The Franklin Gallery. Since the engravings are being issued directly by the Gallery and not through dealers, they can be offered at just $29 each—a very reasonable price for silk-matted, framed color engravings.

And, you have the privilege of trying the first engraving in your home for 15 days *free*. During that time, hang it in your living room, den or bedroom and see how it adds color and beauty to any room. Then, if you decide not to keep it, you may return it within 15 days and be under no obligation.

Each engraving is framed for convenient wall display. And each is fitted with an easel back so that it may be placed on a table, buffet or dresser if desired.

To receive your first engraving on this special free-examination basis, be sure to mail the application below to The Franklin Gallery, Franklin Center, Pa. 19091, by the advance subscription deadline of April 30, 1981.

FREE-EXAMINATION FORM

SONGBIRDS OF THE WORLD

Valid only if postmarked by April 30, 1981.

The Franklin Gallery
Franklin Center, Pennsylvania 19091

Please send me *The Baltimore Oriole* framed color engraving *free* for 15 days. If I decide not to keep it, I will return it within that time and be under no obligation. Otherwise, I will receive a new framed color engraving each month until the series of 8 songbirds is completed. I prefer to pay as follows:

( ) Bill me $29.* for each color engraving with shipment.

( ) Charge my credit card at $29.* for each color engraving, after its shipment (check one)
( ) American Express ( ) Diners Club
( ) Master Charge ( ) VISA

The World's Most Comfortable Shoe!

The Famous CosmoPedic™

Not $50 Not $25

Here Only $14.99

Genuine Leather
Smooth or Sueded

TRY THEM AT OUR RISK!
Return Within 14 Days for Money Back

NOW! BLISSFUL COMFORT MORNING TO NIGHT! The closest thing to going barefoot! Handsomely-styled CosmoPedic shoes are the ultimate in comfort . . . and quality-crafted with features you'd expect to find in a $50 or $25 shoe! Luxurious genuine leather uppers in deer-tanned smooth or sueded leather are incredibly soft, yet amazingly shape-holding. The unique CosmoPedic arch support assures comfort thru long hours of standing or walking. A stitched collar prevents annoying chafing around the ankles. And for that walking-on-air feeling . . . cushioned insoles and crepe soles pamper your feet from heel to toe! In Tan or Black smooth leather; Brown or Sand sueded leather . . . just $14.99!

for Men and Women

Men's ½ sizes: 7 to 12, also 13
Width: C, D, E, EE, EEE
Women's ½ sizes: 5 to 10, also 11
Width: B, C, D, E, EE, EEE

JACK DANIEL SQUARE GLASS SET

Mr. Jack Daniel was the originator of the square bottle for his whiskey and always wanted to have a matching square glass. Well, here it is! This hefty square glass (each weighs 14 ounces) is the perfect companion to a bottle of Mr. Jack's finest. The inside is rounded to make drinking a pleasure and the original design is fired on for good looks and durability. My $15.00 price for a set of 4 glasses (8 oz. capacity) includes postage.

Send check, money order, or use American Express, Visa or Master Charge, including all numbers and signature.

(Tennessee residents add 6% sales tax.) For a color catalog full of old Tennessee items and Jack Daniel's memorabilia, send $1.00 to above address.

trees apparently required catastrophic disturbance of the previous vegetation by hurricane. Beech also displays a most intriguing pattern of establishment. No seedlings appeared until 1810, when the oldest white pines were 155 years old. Thereafter, a successful beech seedling appeared roughly every ten years, arriving, not as a result of major storms, but through some conjunction of unknown events. Thus, what spells destruction for one species leads to the accession of another; disturbance lies in the eye of the beholder.

Disturbance may also take the form of biological forces, such as disease, which can be especially disastrous to plant communities because their effects can multiply in time, and grazers. Heinselman noted that mature stands of balsam fir are particularly susceptible to outbreaks of spruce budworm, which devastate many acres and create fuel for fire. On the prairies, the annual migration of buffaloes undoubtedly had an immense impact on the vegetation. Some herds numbered four million, and their passage must have left a swath of deeply cut sod, with local patches of packed grass and manure in the vicinity of large congregations.

The scale of disturbance need not be vast and catastrophic. William Platt, a plant ecologist working in virgin prairie in Iowa, identified a community of plants that grow on mounds of soil created by badgers digging for ground squirrels. These herbaceous perennials—showy goldenrod, false boneset, common milkweed, and lobed cudweed—flourish on badger diggings but are relatively rare in the surrounding prairie. They appear well adapted to this transient habitat: all grow rapidly and produce early and abundant seed capable of colonizing other local disturbances. Thus, even the modest scratchings of a mouse may provide sufficient space in a sward of white clover for a ragweed seedling to escape from the shade of established vegetation.

Once we shift our perception of disturbance from the scale of the plant community to the death of the individual plant, disturbance is ubiquitous in all natural communities. A devastating hurricane lethal to hemlocks leaves young maples untouched and lays a seedbed for black birch. A local rabbit warren brings a palatable grass to the brink of extinction, but the adjacent brier patch thrives. Disturbance

does destroy life, and in this capacity we can define it as an unexpected increase in the probability of dying. But it is also intimately associated with the establishment of new individuals. Destructive action creates space where there was none before, and in nature no space lies vacant for long. There are always species with subtle adaptations for recognizing those conditions favoring growth into the canopy foliage.

Just how subtle these adaptations may be has been demonstrated by John Harper and his students at University College of North Wales, who term such local disturbances safesites for seedlings. These investigators laid down a uniform garden seedbed in which they sowed seeds of three related species of plantains—the great, the ribwort, and the hoary plantain—over the moist soil surface. To create microsite disturbances, they dug holes to different depths in the soil or left small, wooden boxes with their sides partly projecting above the surface or laid sheets of glass flat over the seeds. Two months of germination revealed obvious differences among the species. Few seedlings were found in control sites without any soil disturbance. The hoary plantain germinated vigorously under glass, probably because of the warmer temperatures and intense moisture. The great plantain was somewhat uncooperative, preferring to appear in locations just outside the local disturbances. The ribwort plantain favored boxes and deep holes. Most remarkable were two large clusters of ribwort seedlings vigorously sprouting from a pair of earthworm casts left at the surface. Undoubtedly all these objects mimic the kind of natural microsite disturbances that favor the establishment of new individuals, and each species is adapted to slightly different circumstances.

This view of disturbance, scaled to relate to the biology of particular species, is a very different interpretation of nature from Clements's view of stable, permanent climax vegetation. Sudden and unpredictable upheavals are prevalent in nature, and the deaths of some individuals are soon followed by the establishment of others. From the perspective of the individual plant, the world appears closer to Turner's vision.

CODE OF THE
QUIPU
A Study in Media, Mathematics, and Culture

At the height of their civilization the Incas had no system of writing, but instead used quipus — colored cords, knotted in a special manner — to record and transmit information. Based on a study of quipus found in Inca graves during 19th- and 20th-century excavations, *Code of the Quipu* presents a fascinating anthropological and mathematical study of the problem of interpreting artifacts from a distant culture.

Enter the world of Questers nature tours.

When you travel with Questers, you have the advantage of our knowledge of the travel world. And our experience of the natural world. We are travel professionals. And our only tour program is Worldwide Nature Tours.

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers ... rain forests, mountains, and tundra ... seashores, lakes, and swamps of the regions we explore. At the same time, we include the more usual attractions in touring—the cities, archaeological sites, and people.

The current Directory of Worldwide Nature Tours describes 29 tours varying from 9 to 36 days and going to virtually every part of the world. Included are The Amazon, Peru, Patagonia, Galapagos, Hawaii, Alaska, Death Valley, Everglades, Ladakh, Sri Lanka, Iceland, Scotland, Greece, Australia, and New Zealand. Tour parties are small, the pace leisurely, and itineraries unusual.

Call or write Questers or see your Travel Agent today for your free copy of the Directory of Worldwide Nature Tours.

The African Elephant's Drinking Problem

On the way to the river that is their main source of water, elephants raid crops. Local farmers complain, but ivory hunters are making a killing

by James Allaway

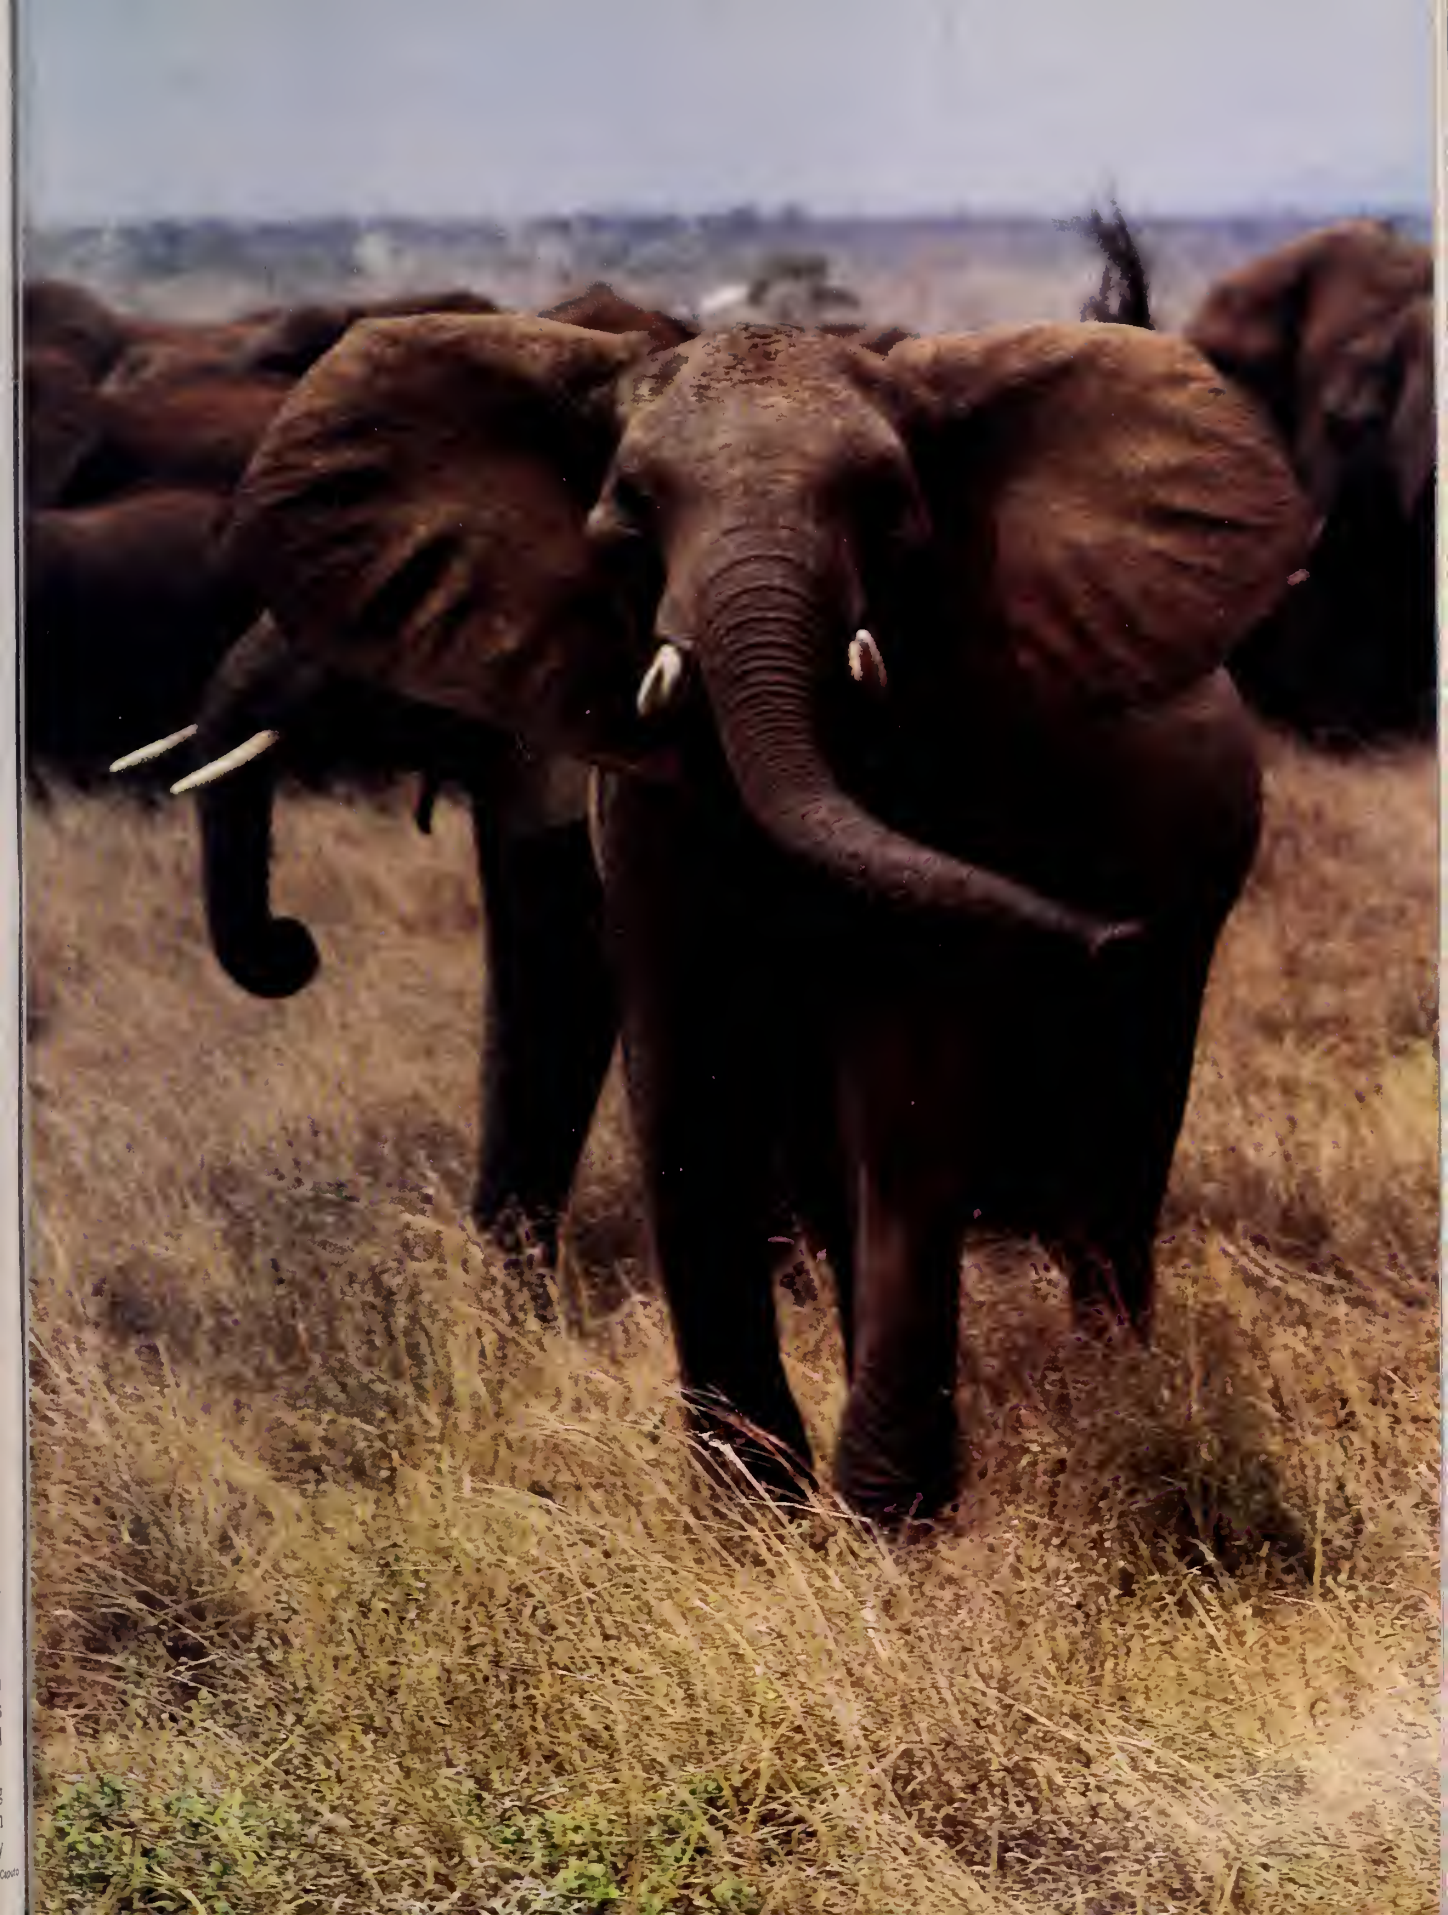
On its meandering journey through the bushland of eastern Kenya, the Tana River—Kenya's longest—has carved a shallow trough in the semiarid plains. The river is virtually the only permanent surface water in this periodically desiccated region, and vegetation grows more richly here. What happens on the river's narrow flood plain is crucial to the region's human population and herds of elephants.

Of all Africa's wildlife, elephants have perhaps the greatest ecological impact and most marked interactions with people. Elephants can greatly affect the structure and species composition of vegetation, thereby influencing the habitats of other wild animals, domestic livestock, and people. They can be significant conduits of nutrient and energy flows. Elephants are also a major tourist attraction, often damage farm crops, and their ivory has for centuries been one of the most highly valued and violently contested products of the continent.

Harsh and mostly undeveloped, the lower Tana region has long been a stronghold of elephants. In recent years it has increasingly come to be a focus for agricultural, ranching, water-resources, and tourism development. Through a study of how elephants use the area and interact with people, carried out in cooperation with the then Game Department of Kenya, I hoped to provide part of the ecological understanding needed to guide the dramatic changes in land use coming to the region. The key elements were the elephants' seasonal patterns of movement and habitat use and their two principal conflicts with people: elephants' raiding of farms along the river and the widespread illegal hunting of elephants.

For much of the 300 miles of the Tana's lower course, its flood plain varies from a few hundred feet to a couple of miles in width; below the village of Wenje, 57 miles from the coast, it gradually widens into a broad delta extending to the Indian Ocean. Central in the flood plain's importance to elephants is the flux of the equatorial seasons, marked by the sun's semiannual north–south passage. Shifts in the prevailing monsoon winds bring two rainy seasons to the lower Tana, interspersed with extended dry periods. The river, fed by rainfall on the Aberdare Mountains, Mount Kenya, and other uplands of central Kenya, usually floods twice a year. The floods are unpredictable in their magnitude and timing, however, and storms within the region are often localized. Thus the elephants, other wildlife, and people must cope with an environment alternately wet and dry—and often unpredictably so.

Elephants cope by moving over vast areas of the interior—perhaps 15,000 square miles on the west side of the river—when water is available there and falling back on the permanent supply of the Tana River as the interior dries up. This kind of seasonal movement, called a dispersal/concentration pattern, is typical of many water-dependent mammals, including traditional pastoralists and hunters.



During a rainy season and for several weeks afterward, elephants roam over large areas, drinking from the countless shallow depressions and larger rain pans. New grass shoots, herbs, and bushes and trees lush with new leaves provide abundant food. Then, as sun, wind, and drinking by elephants, cattle, and other animals drain the rain pans, the elephants begin to pull back toward the Tana and its flood plain.

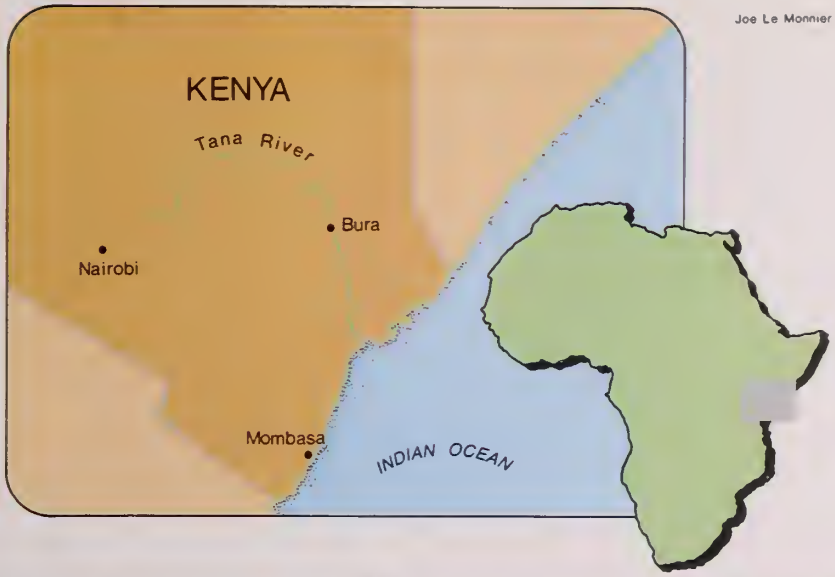
Most basically, the river provides elephants with drinking water. In dry months, however, the river is not accessible along all its banks. Banks are commonly six to ten feet high, and only slope gently enough for elephants to clamber up and down at scattered sites, mostly at the inside of a meander curve or the mouth of an oxbow. This restriction on elephant drinking influences which areas they travel through, feed in, and encounter people.

During dry times the flood plain and nearby areas must also supply the prodigious quantities of plant materials elephants eat. Flood-plain vegetation is an intricate mosaic, shaped by past changes in the river's course, underlying soil conditions, and cutting and burning by people of the Pokomo, the Orma, and related tribes. Patches of forest often occur on higher sites, dense spiny thickets and herbaceous plants in low backwater areas, grasslands on middle elevation flats, and banana plantations or fields of other crops near the river. The complexity is increased by the various stages of regenerating forest and bushland growing on abandoned farm fields and former river channels. Thus the flood plain provides a variety of habitats to feed in, and the elephants use all of them.

Elephants do not limit their feeding to the flood plain, however, even when the only drinking water is there. My

Bob Caputo

observations on the ground and during aerial surveys confirm that in the dry seasons the elephants at times travel and feed far inland, as has been reported for elephants in similar environments elsewhere. Typically, as a dry season progresses, elephants feed increasingly on flood-plain vegetation, and by late in the season, particularly when the drought is severe, this is a heavily used food source.



In addition to food and water, the flood plain provides cover. In cool dark forests and under the shade of scattered trees, elephants find protection from the baking midday sun. They also find refuge from human disturbance deep in dense woodlands or thickets. Elephants rarely stay in the open or near well-traveled human paths during the day.

As elephants concentrate near the flood plain they often raid farms for banana, maize, bean, mango, and other crop plants. They raid almost exclusively at night, usually in the small groups in which they generally travel. They may be turned back by a single-strand fence of vines or barbed wire hung with clattering pieces of metal at the edge of the farm, or they may be repulsed by the farmer and his family shouting, banging on pots, and lighting fires. If, on the other hand, elephants slip into the fields undetected or refuse to be evicted, they can do tremendous damage.

The amount of damage varies greatly. Much depends on the severity of the dry season, the location of the farm (for example, farms near major drinking sites are exposed to more danger), and the farm's defenses. Some seasons, parts of the region have few elephants and farms suffer little; elsewhere damage can range from negligible to total destruction of a crop.

Elephants, along with buffaloes, baboons, waterbucks, and other wild animals, have probably raided farm crops since the animals and farmers first occupied the Tana flood plain together. Damage by wildlife—other species may be as destructive as elephants—often depresses a farmer's crop yield, sometimes disastrously. But wildlife impacts seem to be a secondary influence superimposed on the basic level of production made possible in a particular season by rainfall and floods. If the floods are too low or too brief, crops won't get enough water; if the floods are too high or

Joe Le Monnier

During dry seasons, elephants depend heavily on the Tana River for drinking water. Not all sections of the river are accessible to the elephants, however, as banks are commonly six to ten feet high. Sloping banks, lower left, are situated at scattered sites, and the elephants make extensive use of them to get to the river. Farms located along the paths leading to such drinking sites suffer the most damage from elephants raiding crops. Pastoralists of the lower Tana River also depend greatly on the flood plain when the region dries up because of a lack of rainfall. The river's course, below, is constantly changing, resulting in a mosaic of wet and dry habitats.

Wolfgang Bayer

James Allaway

peak more times than expected, crops drown or wash away. However, the impact of wildlife damage is often magnified since the worst damage tends to occur at just those times when farmers have the fewest reserves to fall back on—late in long, dry periods when crops have been poor.

Conversely, the main direct impact people have on the elephants is killing them. This killing is also often concentrated near the flood plain. Tana elephants have long been hunted for ivory and, to a much lesser extent, for meat. The British colonial government about the turn of the century found a thriving and well-established ivory trade, which has continued to the present. More recently, the Tana was renowned as a prime region for sport trophy elephant hunting, until the nationwide ban imposed on such hunting in 1973.

In the early 1970s, however, elephant hunting escalated with a ten- to fifteen-fold leap in ivory prices from the fifteen to twenty shillings per pound level that had held for decades. (World ivory prices held relatively steady through the mid-1970s but jumped significantly again in 1978.) The style and the impact of hunting changed. Large, well-armed, and well-supplied bands of hunters, many from outside the region, joined the traditional long-bow and poisoned arrow hunters. A factor contributing further to the heavy impact of recent hunting may have been the dry weather during much of the early and mid-1970s, which forced the elephants to spend much time near the river.

How many elephants actually have been killed cannot be known, but by the time of my study (1974–76) the number was already high. In 1976 a ground census of carcasses in a sample area on, and adjacent to, the flood plain found very high recent mortality and much evidence of hunting. The results corroborated other observations and reports on the extent of hunting elsewhere in the region. All strongly indicated that far more elephants were being killed than reproduction could replace.

The elephants are also being affected by change in the native vegetation of the region. Woodlands, thickets, regenerating stands, and especially mature forests—apparently the vegetation types most valuable to elephants—provide quantity and variety of food and also cover. (The scattered patches of mature forest are also essential habitat for other wildlife, including the Tana's two rare monkey species, the Tana mangebey and the red colobus.) But aerial photographs show that during the period from 1960 to 1975, forests on much of the lower Tana flood plain disappeared at an average rate of 1½ to 2½ percent per year. Clearing for farms is thought to be the principal cause. Unlike the situation in some other parts of Africa, elephants in the Tana region did not appear to be doing significant damage to the overall status of the vegetation.

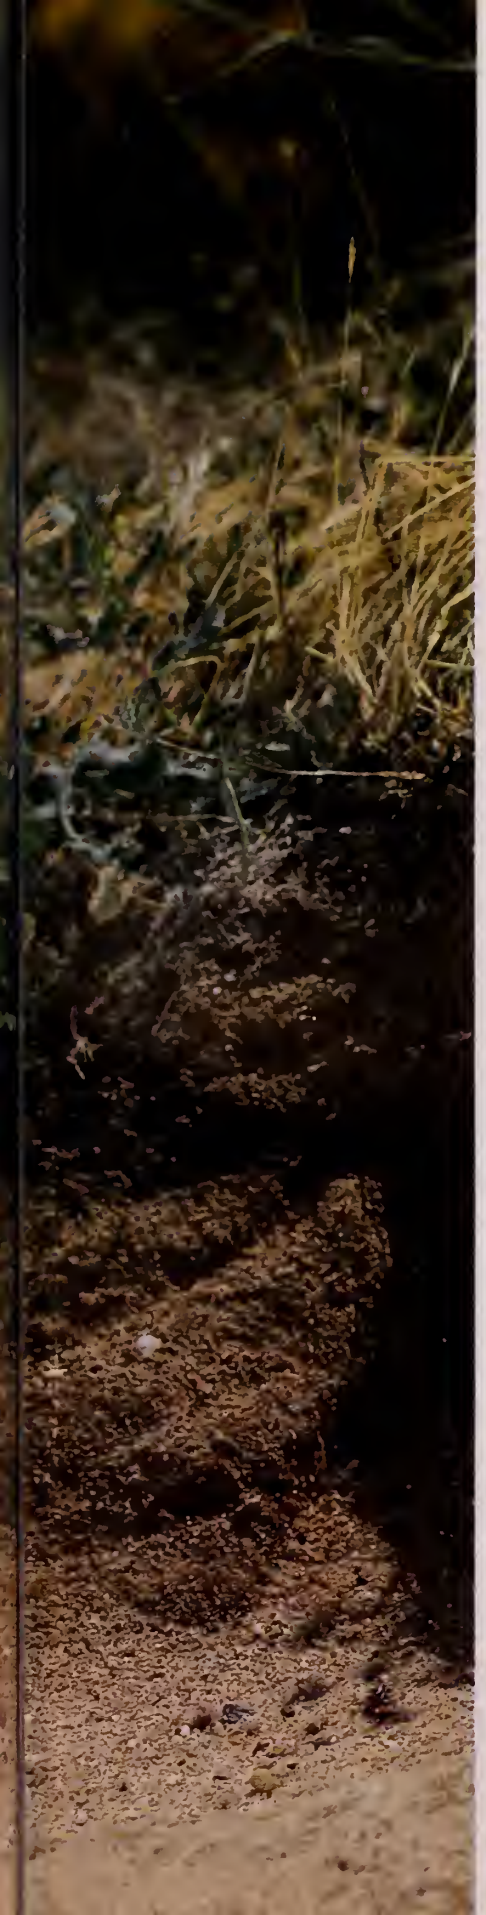
Certain flood-plain resources that elephants need are relatively scarce, particularly safe drinking sites, mature forests, and refuges secure from disturbance.These are likely to become scarcer still, as human land use expands and intensifies. Access to drinking sites may be cut off by new farms and expanding villages; forests and regenerating woodlands may be cleared for farms, selectively cut for dugout canoes and building poles, and scorched by fires; refuges may be penetrated by hunters and exposed to generally increased human activity.

More drastic alterations to the Tana region's natural conditions and processes may result from major economic development activities under way. Some analysts think hydroelectric power generation dams and water-supply reservoirs upstream (some in operation for several years) may change flood patterns and low-water levels. If this happens, the present dynamic character of the river could be tamed, and everything that has evolved with, or adapted to, the river and its flood plain could be affected—forests and grasslands, elephants and monkeys, farmers and pastoralists.

A more immediate impact on elephants will result from the large irrigation project being built near Bura, in the middle of the region. Elephants will lose not only the project area (just off the flood plain) but, more important, possibly the flood plain behind it, as well as the whole area between the river and the planned main canal supplying irrigation water from many miles upriver. The canal is designed to permit crossings by elephants, and water holes are being constructed in the hope of satisfying the animals outside the project. Whether these efforts will succeed is not certain. Considering the importance of flood-plain vegetation to elephants and the frequent aridity of the Bura region, a reduction in elephant numbers in the vicinity seems a likely result of the reduction in flood-plain resources. The vast increase in human activity accompanying the scheme (it is projected to support a population nearly equal to the entire region's present population) is likely to have severe and even broader repercussions. Furthermore, some observers fear there will be effects on the river from offtakes of water for irrigation and from saline or chemically polluted discharges back into it.

Our understanding of elephants, traditional human land use, and other aspects of natural ecological systems in the Tana region is only sketchy. But some basic facts and principles are known that can help guide future management of natural resources, whether the objective is to protect elephants and forests or to assist farmers and pastoralists. The Tana region until very recently was little altered by development. Now change is coming, and anticipating and controlling its impact can be aided by understanding how natural systems worked in the past and seeing just what is at stake. For elephants, for other wildlife, and for people—for everything that depends on the present character of the flood plain—much is at stake.

Good seasonal rains have fallen on the Tana region most years since my field research. But as the inevitable, extended dry periods recur, the elephants that remain must return to the river. Again the flood plain's water and vegetation will become paramount in their existence. Conflicts with people can be expected to intensify as human use of land increases and the price of ivory continues to rise. The elephant's prospects are uncertain. □



Bob Caputo

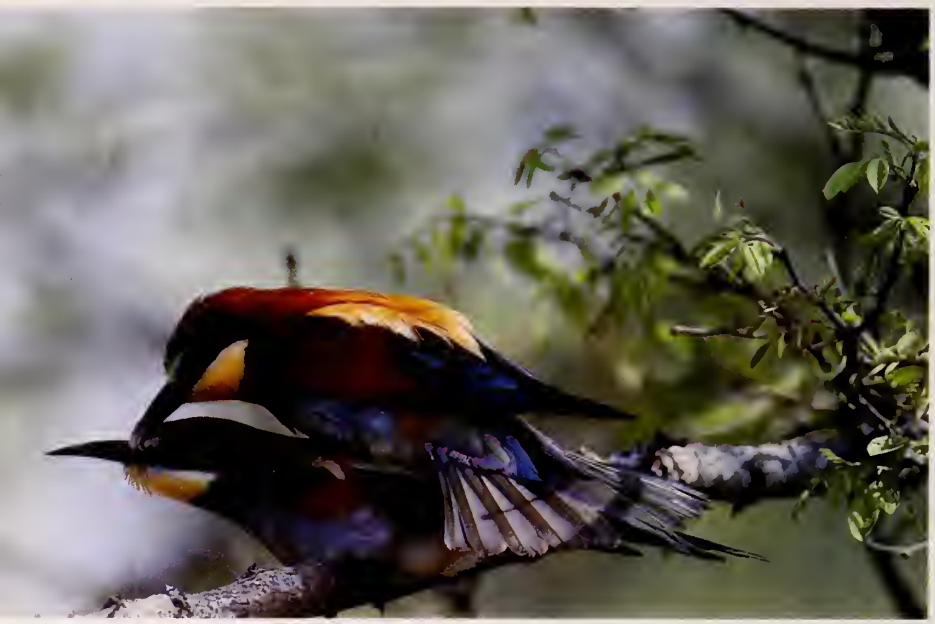
The 1,500 percent increase in the price of ivory during the past decade has led to the massacre of elephants throughout Africa. Hunting elephants for their ivory has a long history in the Tana River region; high prices, the use of modern weapons, and poaching raids by Somali tribesmen have accelerated the slaughter. The huge animals make easy targets, particularly when they are concentrated on the Tana River flood plain during the dry season. Hunters typically hack the tusks out of the elephant's skull, left, leaving the rest of the body for scavengers or simply to rot.

Wolfgang Bayer

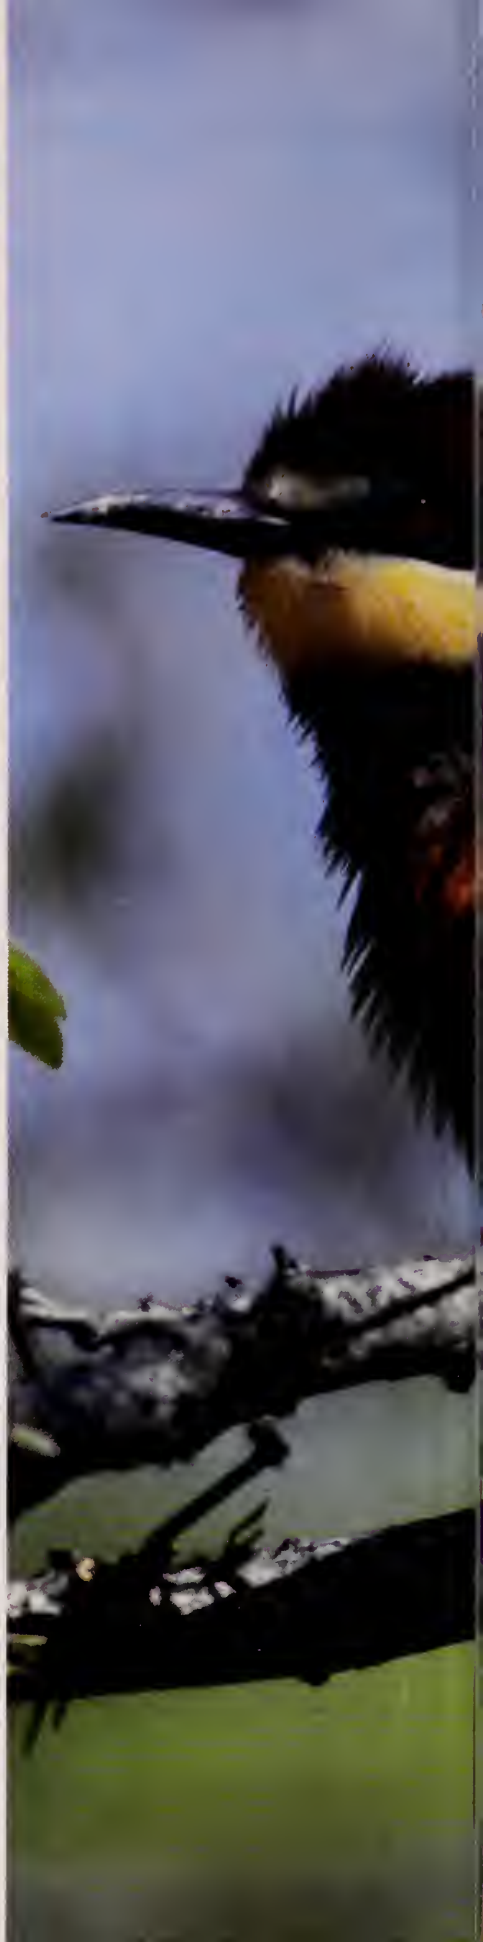
Bees for the Birds

photographs by Javier Echevarri and Mila Olano

The European bee eater, *Merops apiaster*, belongs to an Old World family of brightly colored, insectivorous birds. Many of the insects bee eaters catch—bees and wasps primarily—are venomous, and all species are adapted, in behavior and morphology, to their hazardous prey. The birds' long, pointed wings fit them for twisting flight, while their long, inflexible bill, decurved to a sharp point, is useful in catching stinging insects.



Bee eaters hunt while in flight or in dashes from a perch, usually a tree branch or telegraph wire. Large species, such as the eleven-inch-long *Merops apiaster*, may hunt from as high as 300 feet and sometimes feed in flight, mostly on soft-bodied, nonvenomous insects. Before eating venomous prey, however, the bee eater returns to a perch to remove the poison. After manipulating its catch into a good working position, the bird raps the insect's head sharply on the perch; then, altering its grip, it rubs the insect's abdomen on the perch to force the venom out. The bird can then safely eat the insect or deliver it to the young waiting in the nest (below).



All bee eaters are single brooded and nest in burrows, excavated most often in a bank or cliff, occasionally in level ground. *Merops apiaster* breeds from western Siberia and Kashmir to North Africa and the Iberian Peninsula, where these photographs were taken. It generally nests in dense colonies; sometimes, however, only a few pairs are seen nesting in an area.

After arriving from their wintering grounds in tropical and southern Africa and northwestern India, a breeding pair of European bee eaters choose a nest site and begin to excavate. They loosen the soil with their bills, then use their

legs to kick it out of the tunnel. In this manner, they dig a more or less horizontal burrow, usually several feet long, with an unlined nesting chamber at the end.

Courtship among European bee eaters is straightforward. After assuming a precopulatory upright stance, they may perform ritualized gestures. One bird may bow its head several times, as if it were rapping an insect against the perch, its bill almost striking the perch near the feet of the other bird. Copulation (above) is also often preceded by courtship feeding.

Both male and female incubate the eggs and care for the young. They never clean the nest, so the chamber eventually is cluttered with regurgitated pellets of indigestible matter, primarily sclerites, and the walls become coated with dried feces.

Toward the end of the breeding season, the accumulation of filth in the burrows and, in dense colonies, the congestion of the population result in ectoparasitic infestations. Bee eaters engage in a variety of sun- and dust-bathing postures, partly to relieve their lousiness. One sunning position, common to all bee eaters, involves perching with the mantle feathers fluffed up (right) to expose the skin to the sun's rays.

Rebecca B. Finnell

Street Urchins of Colombia

Amid the poverty of overpopulated cities, thousands of young children learn to survive through their own ingenuity

by Kirk Felsman
photographs by Anthony Boccaccio

The streets of major cities have always served as both theater and battleground for the children of the poor. Nowhere is this more apparent than in present-day Colombia, where thousands of street children, so-called gamins, struggle to survive with little or no support from the traditional institutions of family, church, school, or state. Young ragamuffins, darting in and out of traffic, begging in open-air restaurants, singing for change on city buses, bathing in public fountains, or simply curled up asleep together, sometimes along with stray dogs, are all too common sights. The street urchin has become so much a part of Colombian society that a recent performance of the National Ballet Company included a piece entitled *Gamin*, while a popular soap opera on the same subject is broadcast most evenings in the capital city of Bogotá.

The word *gamin* comes from the French, meaning "urchin." It is but one of the by now pejorative names these children have long endured. One can also hear *chinos de la calle* ("children of the street," from the Quechua *chino*, "child") and *chinches* ("bedbugs"), used to refer to the smallest waifs, as young as age five. The children naturally seek to be recognized and known as individuals, preferring their own names and nicknames. But they also find strength in a shared identity. For a collective name, most prefer to be known by some variation of *muchachos* ("boys") *de la calle* or *niños* ("children") *de la calle*.

Street children are not unique to Colombia. Major cities in Brazil, Mexico, Turkey, India, and other countries face like problems on a similar scale. For historical comparison, one recalls the *scugnizzi* ("spinning tops") of Naples and the Barnardo Homes of England, as well as the often described vagrant children in late-nineteenth- and early-twentieth-century Russia and France. The portraits offered up in Dickens's *Oliver Twist*, Morris West's *Children of the Sun*, or Luis Buñuel's film *Los Olvidados* (*The Forgotten Ones*) all evoke common themes. And one of the most serious problems with street children existed in the United States. In 1852, police records estimated there were 10,000 vagrant children adrift in New York City, and similar problems existed in Boston and Chicago. During the period of tremendous immigration and industrialization these waifs were popularly known as "street Arabs." At the turn of the century, the writer, photographer, and reformer Jacob Riis graphically portrayed the lives of these children in his book *How the Other Half Lives*.

Gaminismo, as it has been called in Colombia, is an urban phenomenon linked to the tremendous rural-to-urban migration that has changed the face of Latin America during the past

A storefront alcove in Bogotá shelters a camada, *a loose-knit group of children who sleep together for warmth and protection. Although this group includes a girl, most street urchins, or gamins, are male.*

All photographs from Ocelot

Bogotá is noted for its galladas, *groups of about eight to fifteen children in which membership and leadership are fairly rigid. Although not free of violence and exploitation,* galladas *generally offer their members a measure of protection and emotional support. Outsiders commonly regard them as gangs of young thieves, and it is true that crime may be one of their means of survival. Within the* gallada *sharing a marijuana cigarette, below, the boy with close-cropped hair can be recognized as one who was detained by the police not long before. The police shave the heads of those they pick up, ostensibly for reasons of hygiene, but also to aid identification.*

two decades. This migration has been described by urban planner Edward Popko as a hunger-dictated "push" from the country rather than an economic "pull" from the city. Industrialization has not kept pace with this population shift, which has brought little more than a transfer of poverty from rural to urban areas. The forces of modern communication, transportation, and national education have only heightened the effect. In addition, the trend was exaggerated in Colombia owing to *La Violencia*, a period of primarily rural political violence and banditry that has been likened to a civil war. In search of safety, people were forced toward the cities, and those already there were forced to remain. Only Colombia's coastal regions escaped the worst effects of this disruption, which began in 1948 and lasted at least into the 1960s.

With some 5,000 street children—there are no reliable statistics—Bogotá has been called the capital of the abandoned child. The phenomenon is equally significant in Cali, Colombia's third largest city, where the estimated numbers run to over 1,000. Cali's warmer and drier climate is more hospitable, and it is not uncommon to find children who have traveled hundreds of miles from Bogotá, seeking the milder weather. A sampling of street children in Cali reflects, more accurately than a sampling from Bogotá, Colombia's great racial diversity and dispels the popular myth that only mestizo children (those of mixed Spanish-Indian descent) become gamins. Cali is the nation's fastest-growing city, exemplifying the population pressure and poverty that contribute to *gaminismo*. With a population of little more than 100,000 in the 1950s, Cali has expanded to well over a million people. Migration accounts for most of this increase, and the swelling of slums has placed an unbearable burden on the city's limited public works and social services. Despite an alarming infant mortality rate (92 of every 1,000 babies die in the first year of life, in contrast to 16 per 1,000 in New York City), more than half of Cali's population is under eighteen years of age.

Street children do not all share the same plight, but fall into three general types. The first and largest category consists of those children who maintain some family connection although

Gamins often bear the scars of earlier abuse as well as those of their rugged street life. Many children who work and beg in the streets maintain some family connections. Others are truly abandoned or have chosen to leave home.

they spend the vast majority of their time in the streets. Some work or beg in pursuit of money or goods to bring home after nightfall. Others return home only around religious holidays or when driven by some impulse to make contact.

Carmen (age 6), Elena (age 5), and María (*la niña*, or "the baby") are sisters who beg together within a circumscribed number of blocks in downtown Cali, appearing at the same open-air restaurant every morning. I was struck from the outset by the contrast between their joyful play among themselves and the sad tale they presented together while "working." Coached by her older sisters, cowering a little, hands outstretched, María was always the first to approach a stranger and begin to tell their story. Over the months, I came to know them—and their mother. She was not in a home for the destitute, where her daughters' story placed her, but only a few blocks away, working as a fruit vendor. Mother and daughters traveled daily from the squatter settlement where they lived to Cali's downtown area. The girls would then leave their mother to beg on their own, but they would check in with her periodically and return home with her at night.

With the exception of such girls, who are under some family supervision, the gamin population is almost wholly male. The careful observer may witness a pair of young girls moving together through the streets, almost identical in mannerism and appearance to their male counterparts, or hear of a particular girl who has become a member of a group of boys. More often, however, a girl who lives independently of her family is drawn instead into organized prostitution, accepting refuge and shelter of the most exploitive kind.

Children who have actually been orphaned or physically abandoned constitute the smallest category of street urchins. The misperception that they are in the majority has been fostered, in part, by superficial writing about street life, based on quick interviews. Gamins often readily describe themselves as orphans, both because good storytelling is basic to successful begging and because denial may be the most effective defense against inner pain and conflict.

The truly abandoned child may frequently be the one the family is least able to care for, perhaps because he suffers from some physical impairment or neurological disorder. Such children are least equipped to face life in the streets, but there are few care facilities that can offer an alternative. There is no doubt that many simply perish.

At age ten, Enrique had been in the streets less than a year when I met him. Originally he attributed his deformed hand and severely scarred arm to a terrible bus accident in which he was injured and both his parents were killed. Later, in a quiet, collected manner, he told his true story. When his family first arrived in Cali, Enrique had accompanied his mother as she begged on the streets. Then, gradually, he had begun to beg alone, returning home each evening—to a piece of canvas stretched over a wooden frame, underneath a city street overpass. "One night I came back, and there was another family there. They said my family left at midday. I don't know where they went. So, now I live with the other boys on the street. But I'm not alone." There had been no bus accident: Enrique's deformed hand was a birth defect; his scar the result of a beating.

A child in the final category exists at the opposite extreme: he is the abandoning, not the abandoned, child. Having opted for a life on the streets, such children have little or no contact with their families. While they interact with the other street children, it is they who are the most noticeable and the most difficult to understand.

Not yet ten, Jorge is a veteran of the streets. He believes his family is still in Buenaventura, Colombia's busy southern port, but has never been back to find out. "There wasn't any food to eat, so somebody had to leave." Over time, more is revealed, and particular scars are related to beatings he received from his stepfather. "At first, if I came home with too little, he made me sleep outside, but later, he started to beat me a lot." Jorge's only attempt to fight back, striking his target with a well-aimed stone, was

his last battle; he was warned never to return. "So I left. What else. . . ."

Countless thousands of children remain at home to endure hardships and abuses that children like Jorge refuse to tolerate. The child who strikes out to shape another kind of life for himself often leaves behind numerous brothers and sisters who do not. A mother may describe such a child as the one who "would never listen," who "always asked too many questions," who "would never do as he was told." In short, he is the troublemaker, a child with a difficult temperament in an intolerable environment. Possibly, he is a family scapegoat, who is constantly being given the message to move on. We tend to regard the abandoning, or runaway, child as troubled, even emotionally disturbed. In the case of these particular children, however, leaving home may be a positive, adaptive move toward physical and psychological health.

Girls rarely fall into this category, perhaps because they are more needed within the family. They are expected to care for younger siblings and perform household chores, whereas a more aggressive, independent role is prescribed for young boys. Moreover, in many family situations, the coming and going of *padrastos* ("stepfathers") places different pressures on the boys: there may be competition over the mother and conflict over power or responsibility within the home.

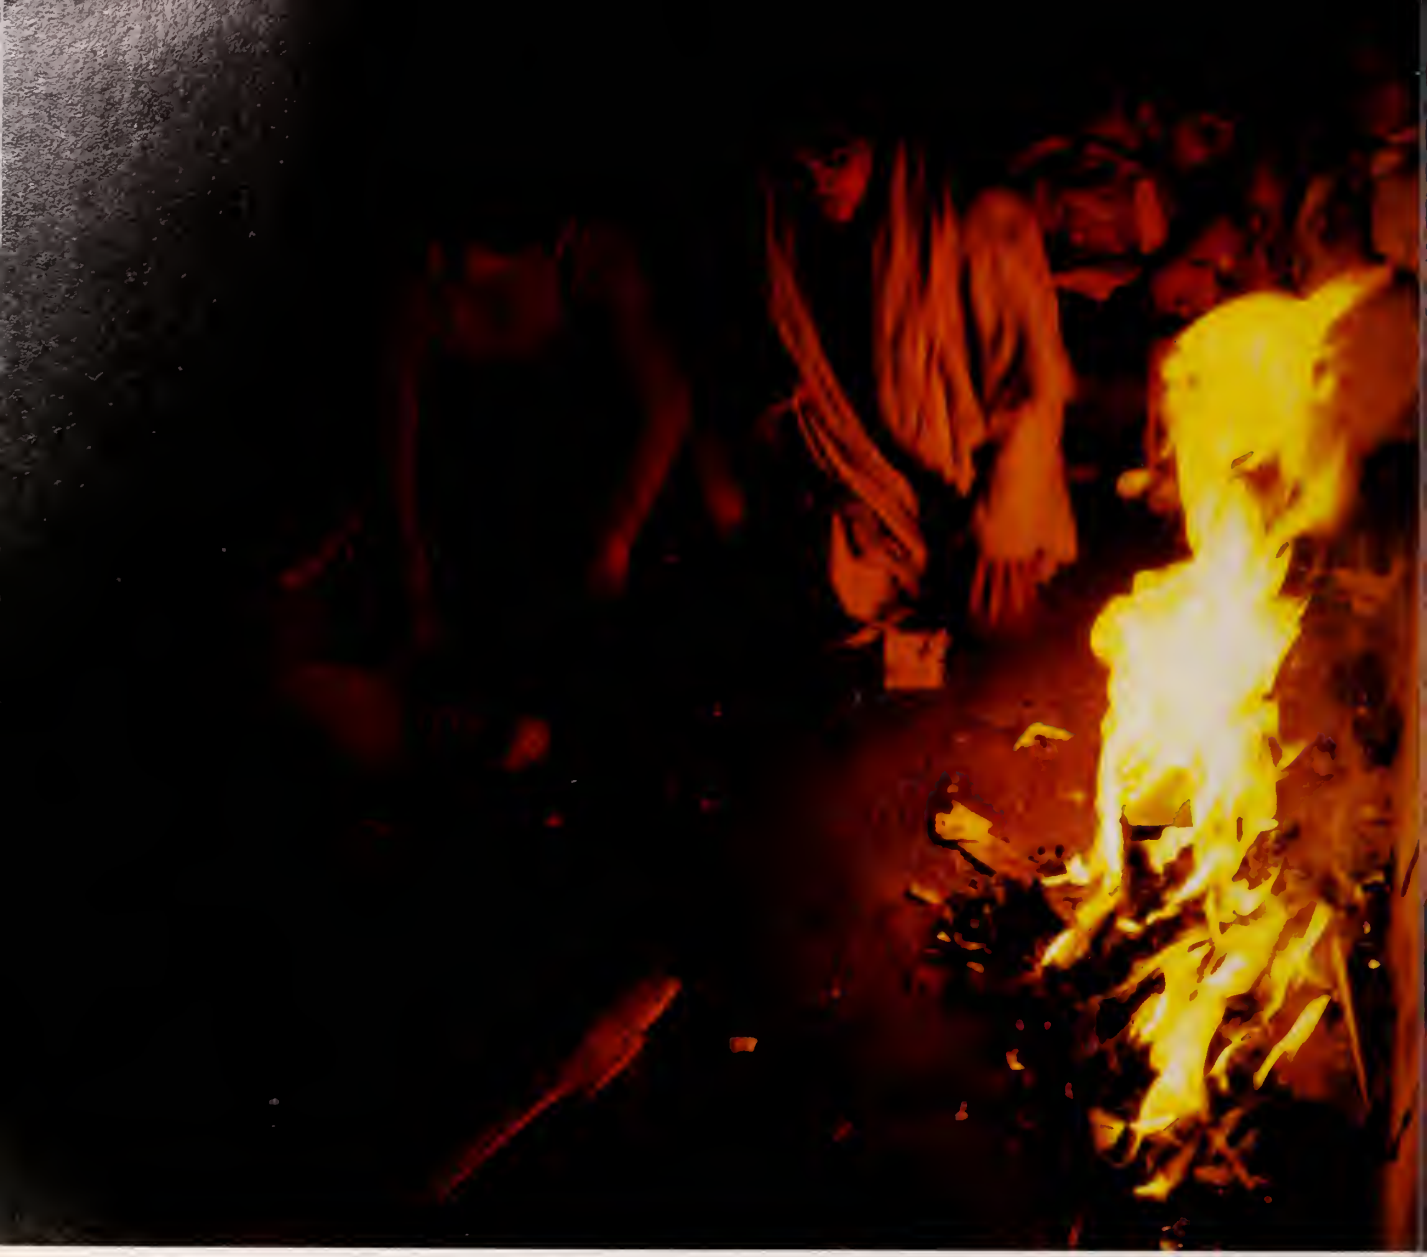
The three types of street children actually overlap, since the plight of an individual child may undergo change or may reflect a combination of factors. And all types of children interact with one another. Survival in the streets is tied to peer support. Bogotá is especially noted for its *galladas* (literally, "roosts"), which offer their members some protection against the ever present threat of crime and abuse. In these groups, which often consist of eight to fifteen children, there is a clear leadership hierarchy, and membership, loyalty, and territory are constant issues. Outsiders often regard *galladas* as gangs of young thieves. There are, indeed, deeply wounded street children capable of great cruelty and outright criminal behavior. But it is important to realize that street children band together primarily to meet emotional and physical needs.

The highly structured *gallada* is almost absent in Cali, but the *camada*

Left: Gamins bathe in a fountain in downtown Bogotá. The climate of the capital city is not the most hospitable for street children. Situated at an elevation of 9,000 feet, Bogotá is often rainy, with an average daytime temperature of 55 degrees. Some children seek out cities with milder weather, such as Cali. There, a child can get by with less clothing, can sleep with less cover, and will find more open-air restaurants in which to beg for food. Below: Often traveling in pairs, gamins hop onto buses to get around a city. The smaller and weaker children may fall off and be killed in the traffic. Sympathetic bus drivers often allow street children to ride inside, where they beg for small change.

("brood" or "litter") is very common. This is a small group of children who sleep in a common area for warmth and protection, seeking refuge in front of large, well-lit buildings or under the sheltered bays of large movie houses. Membership in such groups is loose and informal, with a particular sleeping spot given up, to be reclaimed later.

While exploitation and violence do occur within groups of street children, the older boys usually watch out for the younger ones. On occasion a boy can be observed awakening early, getting up to replace the ragged covering that has worked itself free from a younger companion's shoulder and then returning to his own spot to curl up among those still asleep. The youngest or the smallest child is often the clown, a comic center of attention.



Younger boys typically travel in pairs, bringing to life the "chumship" relationship so well described by the late psychiatrist Harry Stack Sullivan. In what is possibly his first move toward intimacy, a child comes to know himself through another who is similar. Amid the brutality and violence of street life, there exist moments of true warmth, loyalty, and love.

Not all children travel or sleep in groups. There are loners who tend to fend for themselves. Such boys appear tougher, more cautious and aware. For sleeping, they may seek a safer, solitary spot on a rooftop or on the overhang of a building entrance, where they are fully hidden from street view.

Although mistakenly regarded as a separate subculture, the gamins are part of the urban street poor. They are among the thousands of people who labor in the streets at what have been called marginal occupations. Such work ranges from shining shoes and pushing wheelbarrows to raw forms of prostitution, begging, and thievery. The average yield is under three dollars per day, acquired under the worst of conditions. The type of work or "hustle" that occupies these waifs varies with their age and the part of the city they frequent, but is almost always combined with some form of begging.

A main commercial district lined with open-air restaurants and movie houses, such as Cali's Avenida Sexta ("Sixth Avenue"), represents a major resource for the gamin population. Approaches to begging in restaurants differ, and with a drum (a tin can and stick) or mask such requests become performances of sorts. Receiving acknowledgment that a customer's leftovers are free to be taken, the child may eat a single scrap on the spot or quickly scrape the food into a small can or box, generally to be distributed among companions rather than hoarded for later consumption in private. When things are going well in the street, children can become almost particular about what they will eat. Ironically, most gamins appear to be in better general health than their counterparts in the squatter settlements. Where an urchin's physical stature has suffered from serious malnourishment, it is often a mark of earlier years at home, when many siblings competed fiercely for little food.

Begging is common on city buses.

Allowed to crawl under the turnstile by sympathetic drivers, young boys, often in pairs, will move up and down the aisle singing of their plight, sometimes chorusing, "For I am the child of no one." Begging on buses is common for poor adults as well, especially those with an obvious physical handicap. Thus the practice can be highly competitive, requiring both stamina and imagination. The smallest and most animated child is the least likely to ever return empty-handed. His repeated success brings a measure of equality with the older boys. The teen or twelve-year-old urchin must seek out other resources, and petty crime may arise from necessity.

Work takes many forms. In Cali, some waifs assist the estimated five thousand ragpickers who pull their wooden carts through the streets, seeking out anything collectable: cloth, cardboard, glass, plastic, wood. Some capital or backing is required for the shoeshine boys as well as for those who sell gum, cigarettes (individually from the pack), newspapers, or lottery tickets. Other forms of service work include guarding parked cars, rapidly cleaning windshields at a stoplight, or carrying goods in a marketplace.

At the extreme, work becomes crime, and children do become involved in adult-operated traffic in drugs and prostitution. In Cali, the participation in hard crime appears to be on a much less serious scale than in Bogotá. Crime is likely to take the form of purse-snatching or of stripping mirrors and windshield wipers from parked cars.

Marijuana and other drugs are used, more in Bogotá than in Cali. Drug traffic is in general more prevalent in the capital, where there are more street children and their gang life is more highly organized. In Bogotá, the more formidable city in terms of both climate and competition, drugs can provide relief from the pain of cold and hunger, helping to induce much-needed sleep. Tragically, the most common (because it is the most accessible) and most injurious form of "getting high" is the sniffing of gasoline fumes.

It is at play, though, that the romantic, carefree element of gamin life is truly on stage. The bounding energy of these boys moving through the street or plunging into a public fountain on a warm, sunny afternoon tugs

Left: A group of gamins has paused to build a fire on the sidewalk, tearing the layers of political posters off the adjacent wall. Such fires, which dot the city's streets, parks, alleys, and vacant lots each night, provide warmth and a temporary focal point. Below: Street children who are able to handle the transition to a more normal life may eventually find themselves at La Florida, *a residential program run by a Salesian priest. Children admitted to* La Florida *live in small self-governing groups within a dormitory complex.*

at the more preoccupied, restrained onlooker. The spontaneity and intensity of these activities reveal that these children have not lost the need or ability for play.

Movies are perhaps the all-time favorite source of entertainment for street children, providing a ready-made internal escape. In addition, the lines of waiting ticket buyers are a convenient source of income, and the theater itself offers refuge from the street. After the theater is cleared, its covered bay may serve as the night's shelter, the children spreading their cardboard bedding over the hard, cold tile. Another diversion is gambling, which takes the form of pitching small coins or pebbles. It is done with all seriousness: play is for keeps.

Hopping onto the bumpers of moving buses and trucks doubles as entertainment and transportation. This practice is hazardous, however, and all too often the weak or inexperienced fall off and are crushed by another vehicle. Such accidents go largely unnoticed and certainly unreported.

There are a number of government and private programs that attempt to address what each perceives to be the "gamin problem." Such formal programs are oriented toward either protection or rehabilitation, a philosophical dividing line that is immediately reflected in the services provided.

Consider a small program in Cali that is sponsored by the Red Cross and run by a Peace Corps volunteer. It provides an "ambulance service" in the form of a truck that goes out one night a week to visit areas where some of the children are known to sleep. The staff, equipped with a basic knowledge of first aid, treats many of the common cuts and bruises that, on the street, can so often lead to serious infection. A suspected serious medical problem can also be followed and the possibilities for treatment explored. Food and clothing are occasionally given out. This practice is reminiscent of the ambulance service the Salvation Army provided in Naples after World War II, where nightly distributions of food, clothing, and medical supplies were made from the back of a truck in an effort to reach street children and other urban poor.

Programs geared toward rehabilitation tend to view the child as deviant or delinquent and are generally restrictive and dictatorial in nature. The runaway rate from such settings is extremely high, fueling the myth that these children are uneducable delinquents, born of "bad seed" and beyond sustained help. For example, during the fall of 1979, Cali's largest government program received forty-five new boys in the same month that forty-six boys escaped. Some of the runaways have described it as an "oppressive prison," but its guards and chain-link fences are no match for the determination of children who at such an early age have already broken primary family bonds.

A different orientation has been adopted by an organization in Bogotá, which has a relatively new branch in Cali. This particular program works to preserve the child's sense of liberty and autonomy. The child decides whether to enter, and the door is al-

A cave on the outskirts of Bogotá is one of many places where gamins seek shelter. Some bed down in building entrances, near warm air vents, or in other favored locations. The gamins are just one segment of the urban poor, many of whom live in wretched conditions in crowded squatter settlements.

ways open in case he decides to leave. Interestingly, the most celebrated programs of the Children's Aid Society in turn-of-the-century New York, as well as Father Borelli's program for the street urchins of Naples, used exactly this approach.

For some street children, this program is a hospitality house, the source of regular meals, a clean change of clothes on occasion, and when sought out, a sympathetic ear. It can offer much more, however. After months of visiting, a child may ask to become an *internado*, one who lives in. Over time, he may formally complete the equivalent of a high school education and take up some career training. As they pursue anything from mechanics to music, the talent and intelligence of these children shine. A number are now students at the National University in Bogotá. Yet even this exemplary program is open only to those who are fully capable of the necessary transition. In essence, the program guarantees its own success. Children with severe emotional problems or neurological impairments are left by the wayside early on.

A few of the youngest children who have been placed in government programs may find themselves in a more traditional home through adoption, but this is quite uncommon. In contrast, betwen 1853 and 1890, some 90,000 vagrant children were sent west from New York City by the Children's Aid Society—sent for adoption to a place "where there is more to eat than there are mouths to feed and where a man's children are yet his wealth." A similar policy was followed by the Barnardo Homes of England, which sent thousands of urchins to families in Canada and Australia.

There are rare cases where, on their own initiative, individuals or families have taken in vagrant children and have carried them through the difficult transition from the streets. Others provide assistance through what the children call *contratas* ("contracts"). The *contrata* is an informal arrangement wherein an individual, a store, or a restaurant regularly provides a particular child with food, clothing, and the like, often at a fixed time of day. The child is seldom asked to reciprocate with direct service.

Twelve-year-old Hernán has two *contratas*, one for clothing and one for food. The first is with a woman whose car he guards when she stops at the post office. In addition to the better-than-average tip she gives him for his service, this woman regularly brings him some of her own boy's old clothing. She has contemplated taking him in, but her husband believes it would be difficult, both for Hernán and for them. "So I try to give him a little extra," she says. "It makes me feel good. But I still feel sad for him and for the others." Hernán's second *contrata*, shared by other boys, is with an open-air restaurant. In the late evening he comes to the back door to receive leftovers. The middle-aged proprietor tells me, "You know, I have admiration for the gamins—they are smart and tough, and they make it on their own. I'm like them a little, I've made this business on my own." Later, he qualifies his generosity by adding, "I do ask for something in return. I won't ever chase them away, but I prefer them not to beg in my restaurant. You understand—it bothers my customers, and it's bad for business. That's the way things are. Well, I do what I can."

The gamins deserve respect for their ability to survive, with so little help, against overwhelming odds. But their lives remain filled with pain and suffering. While the streets can fortify, they most often consume. The reality of the gamins' plight must not be romanticized or allowed to disappear into simplistic myths that prevent reflection, responsibility, and action. In particular, these children must not be viewed solely as deviant and in need of rehabilitation. To do so ignores their many strengths and, more important, ignores their most basic need, that of protection. □

THE LUXURY SEDAN THAT DID NOT HAVE TO BE RE-ENGINEERED TO FACE DIFFICULT TIMES.

Will the trials and tribulations of the automobile industry never end?

First came the Environmental Protection Agency and the need to re-engineer to meet the emission requirements.

Then came the gas crises and the need to re-engineer to meet the demands of the gas pump.

Then came last year's money crunch and the most serious challenge of all: the enlightened consumer.

And, with a certain predictability, the luxury sedan makers of the world reacted by bringing forth a slew of "revolutionary" new automobiles, each radically re-engineered to answer the perfectly reasonable question, "What is it that makes an expensive car worth the money?"

A question perhaps uniquely answered by the BMW 528i.

TECHNOLOGY DECADES AHEAD OF THE COMPETITION.

As some of the world's most exalted automobile manufacturers rush to update anachronistic technology—cutting cylinders, resorting to diesel fuel, tinkering with all manner of electronic gadgetry—one caveat should be observed: evolution, as any automotive expert will testify, is always far preferable to revolution. We are, after all, dealing with a machine made up of several thousand parts.

Which is perhaps the most convincing argument for owning the BMW 528i. A car developed and refined over two decades. An engineering concept so basically sound that an era of automotive restrictions has, if anything, proven it to be even more correct.

A SYNERGISTIC USE OF ELECTRONICS AND MECHANICS.

Car and Driver magazine has seen fit to predict, "In the not-too-distant future, most cars will be equipped with some form of electronic fuel injection simply because it is a more precise fuel-delivery system."

Far from just beginning to dabble in the sophisticated arena of electronics, BMW installed such a system in 1975.

With every engine revolution a computer receives and assesses signals from electronic sensors within the 6-cylinder engine itself. Then instantly determines the precise air/fuel mixture to be injected into the cylinder ports—optimizing emissions, fuel consumption and power development to a degree once considered merely within the realm of academic theory.*

So flawless is this marriage of electronics and mechanics that it has resulted in a virtual automotive paradox: an engine which not only performs with more fuel efficiency but with more power as well.

THE DRIVER COMPLETES THE MECHANICAL CIRCUIT.

The interior of the 528i, while classically restrained in style, denies its occupants nothing with regard to appointments or accessories.

But, perhaps because of our involvement with motor racing, we take a wholly different approach to the interior of an automobile.

An approach which includes the driver as a functioning part of the car.

A standard 5-speed transmission (automatic is available) affords the unaccountably unique opportunity to pick and choose one's own gears.

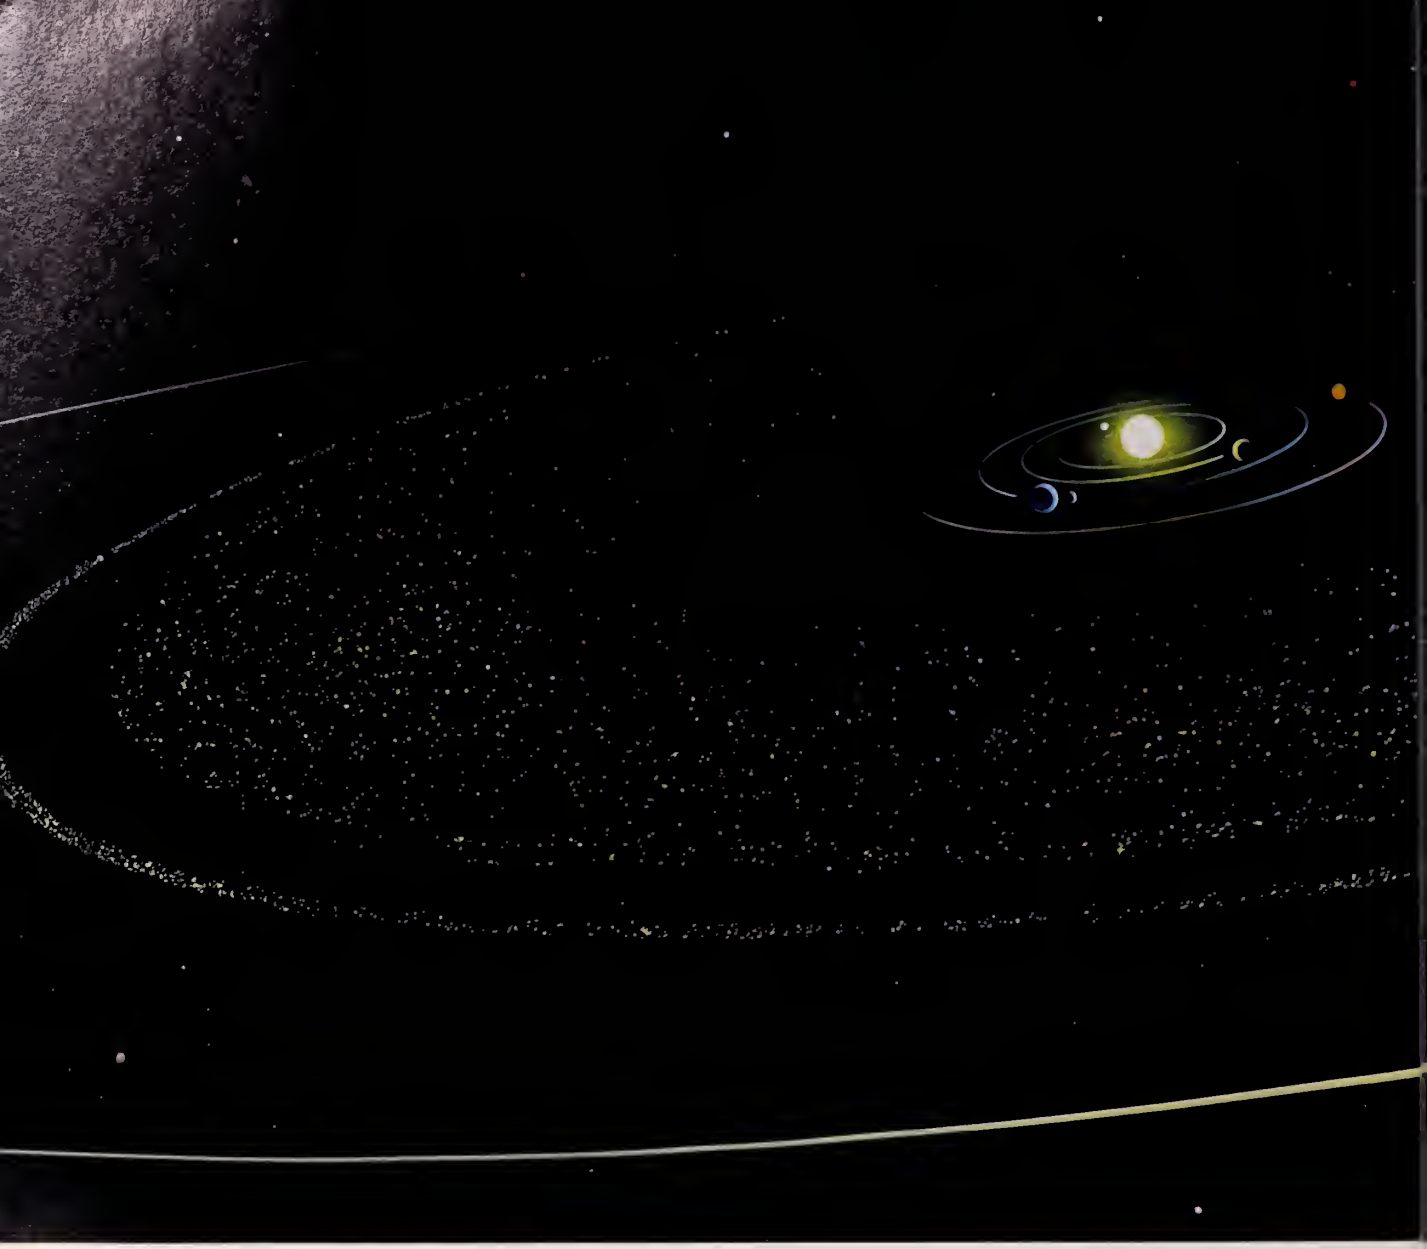
An advanced suspension system—independent on all four wheels—provides what one automotive journalist hailed as "a confidence-inspiring stability." Giving the driver an uncanny feel for the road.

EXTRAORDINARY ENGINEERING IS AN EXTRAORDINARY INVESTMENT.

BMW has always contended that only one thing makes an expensive car worth the money: Extraordinary engineering.

The BMW 528i has itself turned that contention into fact.

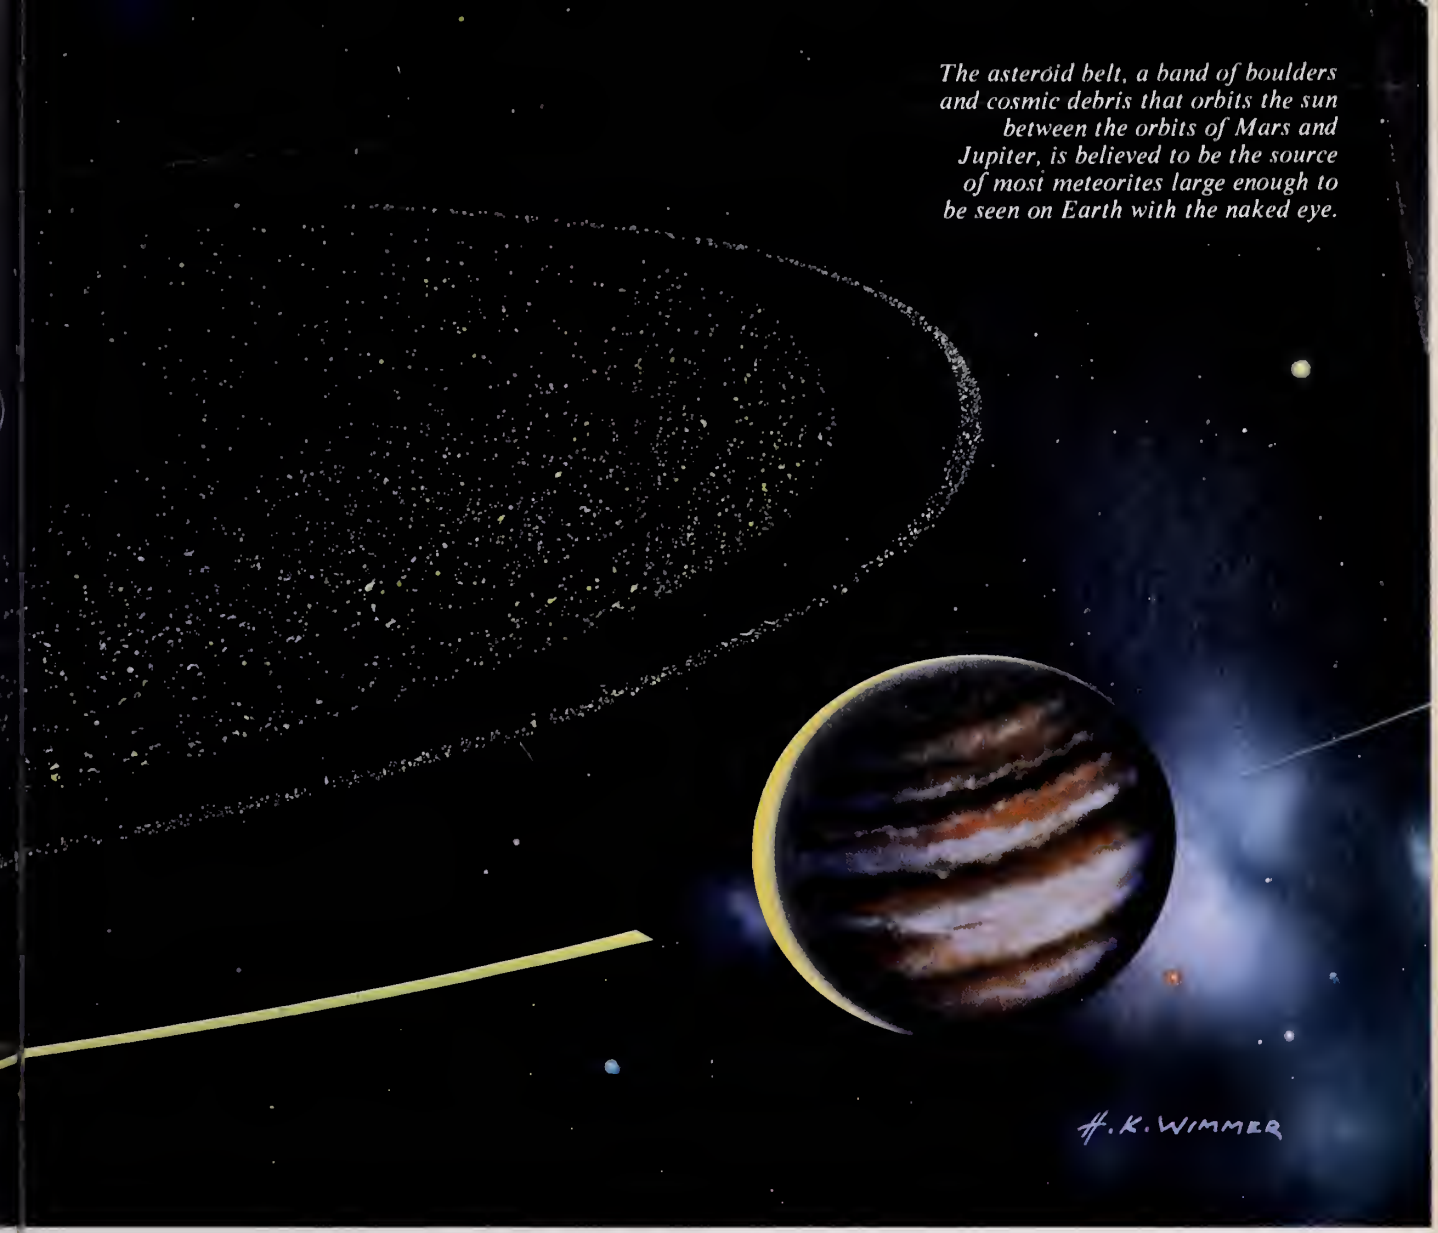
For, according to the Oct. 1980 NADA Used-Car Guide, over the past 5 years, the 5 Series has retained an astonishing 77.9% of its original price.



A figure which neither the Mercedes 280E, nor the Jaguar XJ6, nor Cadillac can approach.

If you find the notion of owning a BMW intriguing, phone your nearest BMW dealer and arrange a thorough test drive.

THE ULTIMATE DRIVING MACHINE.



BMW MOTOR GERMANY

*For example, the BMW 528i (with 5-speed standard transmission) delivers 18 EPA estimated mpg, 30 estimated highway mileage and, based on these figures, an estimated cruising range of 396 mi and a highway range of 492 mi. (Naturally, our fuel efficiency figures are for comparison purposes only. Your actual mpg and range may vary depending on speed, weather and trip length. Your actual highway mileage and highway range will most likely be lower.) © 1981 BMW of North America, Inc. The BMW trademark and logo are registered trademarks of Bayerische Motoren Werke A.G.

From Eternity to Here

A *Natural History* Special Supplement on Meteorites

The asteroid belt, a band of boulders and cosmic debris that orbits the sun between the orbits of Mars and Jupiter, is believed to be the source of most meteorites large enough to be seen on Earth with the naked eye.

Meteorites are pieces of rock that rain from the heavens. It may be difficult to believe that rocks can fall from the sky—especially when looking at such large objects as the Ahnighito, the 34-ton hunk of Cape York meteorite that is the centerpiece of the new Arthur Ross Hall of Meteorites at the American Museum of Natural History. Nevertheless, rocks do drop out of the sky. More than 3,000 of them have been collected and placed in museums and university laboratories around the world, where they can be gazed at, studied, and analyzed.

For museum visitors, meteorites may be the oldest objects yet seen close up. For scientists, meteorites serve as messengers from the outer realms of space, bearing information about the early solar system.

Many meteorites are now believed to come from the asteroid belt, a band of debris and rocks that orbits the sun about 200 to 300 million miles out, between the orbits of Mars and Jupiter. It is the shape of the meteorites' orbits that suggests that these objects come from the asteroid belt. This view is supported by the fact that the asteroid belt marks the outer limit of the terrestrial, or rocky, planets: Mercury, Venus, Earth and its moon, and Mars. Beyond the asteroid belt, the only rocky bodies known are the small satellites, or moons, of the gigantic gas planets such as Jupiter and Saturn. It is important to note, however, that not all meteorites come from asteroids. There are also tiny meteorites, about the size of dust particles, that are believed to come from comets.

Whatever their origin, meteorites have been classified according to their most obvious physical characteristics into three main types: stony meteorites, composed predominantly of silicate minerals; iron meteorites, made up, as their name suggests, almost entirely of metallic iron; and stony-irons, which are half stony and half metallic. Within these main types there are many subdivisions and differences.

Type of Meteorite	Approximate Percentage of Known Meteorites
Stony — chondrite — ordinary chondrite	72%
Stony — chondrite — carbonaceous chondrite	13%
Stony — achondrite	8%
Iron	6%
Stony-iron	1%

A polished ultrathin section of an ordinary chondrite shows one of the small, rounded masses known as chondrules that are typically embedded in this type of meteorite. Ordinary chondrites are the most numerous of all known meteorites. This one fell in India in 1976.

R. Beauchamp; Batelle Pacific Northwest Laboratories

The stony meteorites, in particular, are subdivided into two major groups, chondrites and achondrites. These designations come from the small, round objects called chondrules that were discovered when meteorites were first studied under a microscope in 1869. Chondrules are tiny blobs of mineral material—glass and crystals—about one millimeter in diameter. The chondrites contain chondrules; the achondrites do not.

Although both the chondrites and the achondrites are stony meteorites, they are very different in appearance. No terrestrial rocks contain chondrules, and therefore no earth rocks look like the chondrites. The achondrites, on the other hand, often look like those formations of igneous earth rocks in which small angular fragments are piled together in a chaotic heap whose gaps are filled with still smaller fragments. This kind of rock formation is called a breccia, and breccias similar to those of achondrites were brought back from the moon by the Apollo and Luna missions. Studies of the lunar specimens have shown that a single breccia can include fragments of many different types of rock instead of only one. Similarly, a variety of extraterrestrial rock types will often be found in a single brecciated achondrite, so that the meteorite is a particularly rich source of information. The chondrites are the most abundant of the known meteorites, making up about 85 percent of the identified finds. Achondrites constitute about 8 percent of the total.

The chondrites are themselves further divided into ordinary chondrites and carbonaceous chondrites. Both kinds are made of primordial and undifferentiated (that is, unseparated) material but there are important differences between them. Carbonaceous chondrites are the most primitive of all the meteorites, containing complex organic molecules that may, under appropriate environmental conditions, be the precursors of life. They also contain water bound structurally to their minerals. In addition, carbonaceous chondrites have inclusions that were created at high temperatures: these are the very earliest minerals, produced when the solar nebula, a hot cloud of gas, began to collapse and condense to form the chondritic materials from which all the planets and the sun evolved. Ordinary chondrites are also primitive, being about 4.5 billion years old, but unlike the carbonaceous chondrites, they contain neither organic components nor water. They are presumed to record later chapters than the carbonaceous chondrites in the evolution of the solar system.

Iron meteorites are very different from stone ones. There are no rocks on the surface of the earth that look like them. The only place on the planet where anything similar might be found would be 5,000 kilometers beneath our feet in the earth's semimolten core. Because metal is less brittle than rock, iron meteorites are less likely than stony ones to break up as they travel through the atmosphere, so that very large pieces can sometimes be found. The iron Ahnighito, for example, is the largest piece of a meteorite on display in any museum in the world. It is not, however, the largest meteorite that has ever been found. An iron meteorite called Hoba, which may weigh more than 60 tons, lies where it fell in Namibia (formerly South-West Africa); it is too big to be easily moved. More than 500, or about 6 percent, of all known meteorites are irons. The stony-irons are a smaller group than either the stones or the irons. Only about sixty-five to seventy of the known meteorites are in this group, and like the irons, the stony-irons do not resemble any rocks of any type found on the earth.

The studies that are currently being conducted on meteorites are largely devoted to determining their composition, their age, and the processes by which their components have been differentiated. Composition and processes of differentiation are determined by means of chemical analyses. Age is determined by measuring the abundance in a meteorite of certain radioactive isotopes that have known rates of decay and can serve as clocks.

The articles that follow in this Special Supplement of *Natural History* describe the improved understanding of the nature of meteorites that has resulted from these ongoing studies and the role that meteorites have come to play in informing scientists about the development of the planetary system. The oldest meteorites yet dated are about 4.6 billion years old, some 100 million years older than the earth or the moon. Since they predate anything found on the planet, they can help fill in the earliest chapters of our own history that have been obliterated on the earth. □

Long-playing Records

Invaluable clues to the history of the earth and the moon come from the study of meteorites

by John A. Wood

Meteorites are not merely curiosities that fill our museums. They are crumbs and scraps left over from the formation of the solar system, and they retain a record of the things that happened at that time.

Our sun was formed by the drawing together of wisps of gas and specks of dust from the space between the stars. As a byproduct of this process, vast numbers of lumps of earthy grains and icy material were left spinning in orbits around the infant sun. The orbits were more or less round and concentric, lay in nearly the same plane, and all the lumps revolved in the same direction, so there was an organized motion of the ensemble like that of a thin, dark disk turning slowly about the sun. The icy lumps were probably present only in the outer

Before the earth's crust solidified, meteorites bombarding the planet may have sent up fountains of lava. In Chesley Bonestell's painting, "Formation of the Earth's Crust," a swollen moon looms on the horizon.

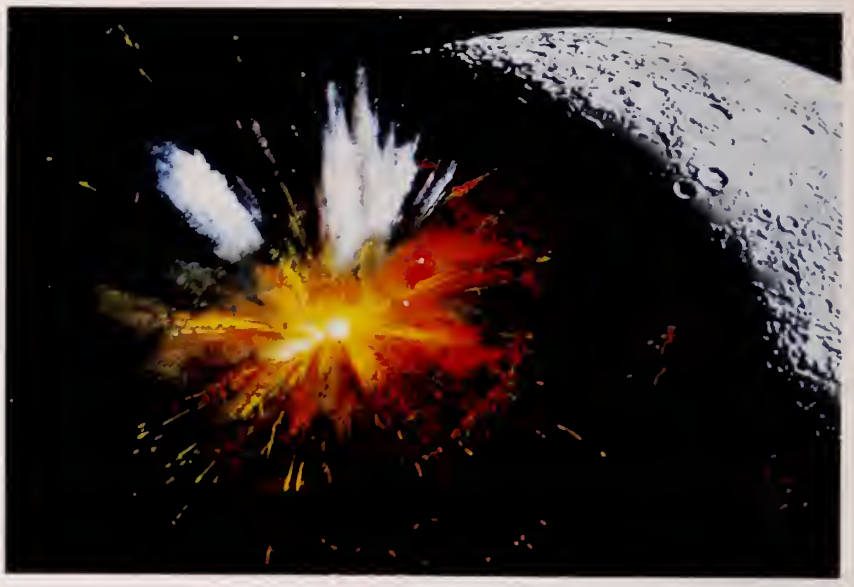
Future Life Magazine; Chesley Bonestell

reaches of the disk, far from the sun's heat.

At this point of development the earthy lumps were still random mixtures of those chemical elements that had been present in the interstellar dust grains that were drawn into the solar system. Actually, various complicated and interesting things had happened to the interstellar dust grains by now, but there had been no major sorting-out, or fractionation, of the chemical elements.

As their orbits carried these lumps of primordial material slowly past one another, they tended to clump together and gradually build up into larger masses. The biggest of these aggregations, or planetesimals, attained diameters of several hundred kilometers. Planetesimals represent a stage halfway between lumps and planets.

Some of the planetesimals, probably the largest ones, grew very hot inside. The source of the heat is poorly understood, but there is no doubt the heating occurred since we can still see the effects it had by examining meteorites. The planetesimals in question melted inside, lava erupted on their surfaces, and the nickel-iron metal they contained melted and sank to their centers, collecting into dense cores.



The aggregation of lumps and the growth of planetesimals continued, but the orbital motions of these objects became more disorderly. Instead of merging into a single, larger body when they chanced to meet, the planetesimals sometimes struck one another at such high speeds that they were smashed and the fragments were dispersed. The planetary disk orbiting the sun now contained a wide diversity of bodies: some were still growing, others were fragments of once larger bodies; some still had their primordial, unfractionated composition, others were fragments of the lava layers and metal cores from planetesimals that had melted and fractionated.

Eventually, all the lumps and fragments and planetesimals in the innermost solar system were swept up into five large bodies: Mercury, Venus, Earth, Earth's moon, and Mars. Over the ages, these objects, acting like giant vacuum cleaners, have totally cleansed their zone of the solar system of primordial crumbs. The materials that were swept up into the planets have been assimilated and repeatedly fractionated by geologic processes—

Another Bonestell painting was inspired by the hypothesis that the huge lunar Mare Imbrium resulted from the collision of a large meteorite with the moon.

Frederick I. Ordway and the Alabama Space and Rocket Center Bonestell Collection

for example, melting and erosion—to such an extent that their original identities are almost totally lost.

Between the orbits of Mars and Jupiter, however, there is a vast expanse of solar system space that does not contain a major planet to act as a vacuum cleaner. In this zone untold numbers of lumps, boulders, fragments, and planetesimals—the asteroids—are still in orbit. This zone appears to be a place where the forces that conspired to draw lumps and planetesimals together into planets failed; the accretion process here never got beyond the planetesimal stage. And since the small bodies of the asteroid belt were never exposed to the vigorous geologic activity of a full-grown planet, many of their earliest properties remain imprinted in them. Thus the material properties as well as the accretional state of the asteroids are records of a time long past, preserved in "deep freeze" like the carcass of a Siberian mammoth.

Orbits are not immutable. Every asteroid is tugged at by the gravity of every planet, as well as that of the sun. Most of the planets are so far from the asteroids that the tugging is insignificant. Sometimes, however, an asteroid passes close enough to Mars or Jupiter (which are closest to the asteroid belt) to be subjected to a substantial tug that somewhat reshapes its orbit. Over a period of hundreds of millions of years, the cumulative effect of a huge number of close passages and gravitational tugs can change an asteroid's orbit so much that the asteroid dives deep into the solar system, crossing the orbits of Mars and the earth in each revolution before it swings around the sun and loops back out to the asteroid belt.

In such an orbit, the asteroid stands a certain chance of colliding with the earth each time it comes around the planet (see "A Near Miss," *Natural History*, March 1981). Actually, it is far more likely to be a small fragment of an asteroid that collides with the earth than one of the kilometers-large objects that astronomers see in the asteroid belt, because small fragments (created by collisions between asteroids) are vastly more numerous than large asteroids. In fact, pieces of asteroids actually do encounter the earth hundreds of times each year. They are slowed down as they penetrate the atmosphere and drop to the ground. Those we find are called meteorites, a term applied to all rocks that fall to the earth from space, whether they should happen to come from the asteroid belt or anywhere else.

All the types of planetesimal material mentioned earlier can be seen in the meteorite exhibit of a natural history museum. The primordial, unfractionated material alluded to is represented by chondritic meteorites, a broad class of meteorites that falls most frequently to Earth and includes the so-called ordinary chondrites. The lava that erupted to the surfaces of melted planetesimals long ago is present in the form of certain meteorites known as achondrites. And iron meteorites are fragments of the cores of similar melted bodies. Is this information a vindication of the theory of planet growth sketched at the beginning of this article? On the contrary; it was principally the study of meteorites that led to the theory.

Do all meteorites come from the asteroid belt? Many meteoriticists are convinced that they do. Nevertheless, there are nagging doubts about the source of the ordinary chondrites, stony objects that are the most abundant group of meteorites. The trouble is that objects in Earth-crossing orbit do not survive for very long. We have two ways of knowing this. First, by measuring the amounts of new isotopes that have been created in a meteorite by cosmic rays in space, we can learn how much time has elapsed since the meteorite was knocked out of its parent asteroid. (Cosmic rays striking the atoms of a meteoroid alter their makeup, creating new isotopes in the process.) Meteorites are shielded from these cosmic rays as long as they remain buried in the parent body. "Cosmic ray exposure ages" of about ten million years are typically found for ordinary chondrites. This is a very short time compared with the total age of the solar system—four and a half billion years.

Second, we can calculate the odds that an object in Earth-crossing orbit will collide with any planet during each circuit of its orbit, and how long the object will last, on the average, before this happens. The answer to how long is, again, about ten million years.

If ordinary chondrites last such a "short" time in Earth-crossing orbits, there must be some abundant source of supply that keeps feeding new fragments into Earth-crossing orbits to replace the losses, otherwise no ordinary

A real lunar crater called Eratosthenes was created by the impact of a meteorite. This photograph was taken during the Apollo 17 mission, the last of the manned lunar flights, launched in December 1972.
NASA

chondrites would be left in these orbits to fall to the earth today. The process sketched earlier, wherein the gravitational tugging of Mars or Jupiter gradually warps the orbits of asteroidal fragments until they cross the earth's orbit, is much too slow, taking many millions of years.

One proposal concerning the source of ordinary chondrites is that they are not derived from the asteroid belt at all, but from comets. Comets are small masses of ice and grains of interstellar dust, in which the "ice" is not only the water ice we are familiar with but also frozen compounds of ammonia and other volatile substances. When comets approach the sun, their ices begin to vaporize and stream out, giving rise to the tails and fuzzy cloudlike masses, or comas, we associate with these objects. Dust particles can be seen streaming away from comet nuclei, as the ices that enclosed them waste away.

Comets are thought to be icy planetesimals that accumulate in the cold outer reaches of the solar system, analogues of the rocky planetesimals that are preserved in the asteroid belt. They were not stored in the early solar system, however, but thrown out of it by the mighty gravitational forces of the outer planets—Jupiter, Saturn, Uranus, and Neptune—when they strayed too close to one of them. Most ejected planetesimals were lost forever to interstellar space, but some remained in slow, coasting orbits around the sun, far outside the orbit of Pluto. These orbits, too, change because of the gravitational tugging on them of stars in the galaxy other than our sun, and every year several icy planetesimals are sent plunging back into the solar system. There, additional gravitational interactions with the planets can place a steady and fairly copious flow of them in Earth-crossing orbits similar to those of the ordinary chondrites. If the nuclei of comets contain large rocks and boulders as well as dust, they would be a possible source of chondritic meteorites.

A serious difficulty with this hypothesis is that the character of the rock in ordinary chondrites shows it has been metamorphosed, or transformed, by high temperatures (roughly 1,000°C) over periods of millions of years. This is hard to reconcile with a former existence in a mass of ice. I have suggested a variation on this theme, namely, that rocky planetesimals from the inner solar system were gravitationally ejected just as icy planetesimals were from the outer solar system. Some of these earthy objects ended up in the same slow orbits as the icy planetesimals, and their orbits subsequently were changed by the same gravitational interactions that govern the comets. Since these objects would move very fast when they enter the inner solar system and do not conspicuously stream gas, they would escape the notice of astronomers. Such objects could be fed into Earth-crossing orbits at a rate rapid enough to replace losses, and unlike the icy planetesimals, it is easy to picture them having high-temperature histories.

Whatever their origin, the extraterrestrial objects that collide with the

earth do so at very great speeds, between ten and thirty kilometers per second. (For comparison, a .30 caliber rifle bullet moves at about 0.7 kilometer, or less than half a mile, per second.) They would wreak great havoc if it were not for the shielding effect of the atmosphere we live in.

A meteorite has to punch its way through a column of air having the same cross-sectional area as the meteorite itself, and which is as long as the meteorite's path through the atmosphere. If the meteorite is small, the mass of air in this column will be greater than the mass of the meteorite. In colliding with such an amount of air, the meteorite is gradually slowed until it falls to the earth at a velocity no greater than if it had been dropped out of an airplane, less than fifteen meters per second.

If, on the other hand, the meteorite is large, the results are different. The mass of the meteorite increases as the cube of its diameter, while its cross-sectional area—and therefore the mass of air it must shove aside—increases only as the square of its diameter. Meteorites larger than a few meters in diameter are heavier than the air they must displace, so they are not much slowed by it. Very large meteorites strike the ground at velocities greater than ten kilometers per second and explode with greater energy than a comparable weight of TNT.

Fortunately for us, large meteorites are very rare. The objects that come to the earth from space are fragments from collisions between asteroids (and perhaps comets), and collisions tend to create more small pieces of debris than large ones. Thus, for every thousand-kilogram fragment, a collision would result in about ten hundred-kilogram pieces, roughly a thousand ten-kilogram chunks, and so forth. The vast majority of extraterrestrial fragments that collide with the earth are in the small-size, slowable range. But not all the incoming fragments are in this range. Occasionally the earth is struck by meteorites large enough and fast enough to blast huge craters in it. The best example of such a structure is the Arizona Meteor Crater, a pit more than a kilometer wide and a hundred meters deep. The desert around the crater is strewn with iron meteorite fragments. Cosmic rays had generated radioactive isotopes in these meteorites while they were in space; the amounts of these isotopes found to be still present indicate that the meteorite struck the earth at least 2,700 years ago.

Even larger craters can be found elsewhere. They are older and less well preserved than the Arizona crater, having been worn down by geologic erosion. Many are still preserved in the terrain of the Canadian Shield, an expanse of ancient granitic rock extending from the province of Quebec to the Northwest Territories. Craters are abundant in this region. The Shield is geologically stable, erosion is slower there than elsewhere, so craters are preserved longer and tend to accumulate. Luckily no meteorites large enough to form explosion craters have fallen in historical times. (A titanic explosion that occurred in an unpopulated area of Siberia in 1908 left no crater or meteorite fragments and is thought to have resulted from the impact of an icy comet nucleus.)

Nevertheless, the law of averages dictates that extremely large objects must strike the earth at infrequent intervals. These impacts could affect the earth profoundly and on a global scale. Recently it has been proposed that an object roughly ten kilometers in diameter struck the earth 65 million years ago (see "The Belt of an Asteroid," *Natural History*, June 1980). This is not unreasonable, given the present rate of fall of small meteorites and the relative abundances of small and large meteorites. The huge impact postulated is believed to have thrown such a colossal mass of pulverized rock into the air that the atmosphere of the whole earth was clogged with a pall of dust for several years. The dust cut off sunlight from the earth's surface to such an extent that plant life was decimated and as a consequence many forms of animal life became extinct, including the dinosaurs. (The depletion of plant life starved the herbivores, and their extinction, in turn, starved the carnivores.) As evidence of this event, a thin layer of clay—presumably dust deposited from the atmospheric pall—is found worldwide in sedimentary rock strata at the level corresponding to the boundary between the Cretaceous and Tertiary periods, the time when the dinosaurs vanished. The clay everywhere contains trace elements in proportions characteristic of meteorites.

Of course, meteorites also bombard the moon. Since there is no atmosphere there to slow them down, small meteorites as well as large ones blast and crater the lunar surface. Because geologic erosion does not operate on the moon as it does on the earth, lunar craters have persisted and accumulated through the ages, resulting in the pockmarked landscape visible today. The pulverizing effect of meteorite impacts, large and small, created the deep layer of lunar dust that we saw the astronauts walking in during the Apollo missions to the moon. Bits of meteorites can be found in the lunar soil samples they brought back.

There is a possibility that a major meteorite impact on the moon has been witnessed from the earth. In the chronicles of Gervase of Canterbury, A.D. 1178 (translated from the Latin by R.Y. Hathorn), an account is given by five men who had sat outdoors on a July night:

> Now there was a bright new moon, and as usual in that phase its horns were tilted toward the east; and suddenly the upper horn split in two. From the midpoint of this division a flaming torch sprang up, spewing out, over a considerable distance, fire, hot coals, and sparks.

The place on the lunar surface where this would have occurred can be pinpointed, and when photographs of this area taken from the Apollo spacecraft are examined, a fresh, twenty-kilometer-wide crater is found. The formation of this crater (named Giordano Bruno for the sixteenth-century Italian astronomer) may have caused the dramatic spectacle described above, although the calculated probability of such a large impact occurring on the moon during the entire period of recorded history is only about one chance in a thousand.

There is no question, however, that asteroids are out there, though, and must occasionally collide with the earth. Impacts as large as the ones that may have destroyed the dinosaurs and created the lunar crater Giordano Bruno are estimated to occur every thirty million years or less. When will the next one fall? □

Comets are believed to be the main source of the dust particles that produce meteor showers and so-called shooting stars in the night sky. Shown here is Comet Kohoutek, which got brilliant advance notices but did not live up to expectations in 1974.

A Lode of Meteorites

Antarctica has been found to be an exceptional storehouse of these extraterrestrial objects

by Brian Mason

Conventional wisdom would predict that meteorites falling in Antarctica would soon be buried in the ice that covers almost the entire continent and never reappear, except perhaps in the moraines exposed in a few coastal areas. And the chance of recognizing the odd meteorite in the mass of rock debris in a moraine is small indeed.

Prior to 1969, only four meteorites had in fact been found on the whole continent of Antarctica. But in 1969 a Japanese expedition picked up nine meteorites in a small area on the ice-cap near the Yamato Mountains, in the African sector of Antarctica. When that news was first reported, scientists thought that the find might represent a single meteorite that had broken into several pieces during or after its fall. However, mineralogical

examination showed that several different meteorite types were present, representing several distinct falls. The results of that examination have been amply confirmed by additional searches in the same region, in 1973, 1974, 1975–76, and 1979–80, that have yielded more than 3,000 specimens in all.

The early work on the Yamato meteorites was reported at a meeting of the Meteoritical Society in Davos, Switzerland, in August 1973. William A. Cassidy of the University of Pittsburgh, a scientist with long experience in the search for meteorites, who attended that meeting, was immediately struck by the evidence for some concentrating mechanism—a process that would explain the occurrence of several different meteorite types in a small area—and deduced that special conditions unique to the Antarctic ice-cap must be responsible. He concluded that similar conditions should exist elsewhere in Antarctica. The success of subsequent expeditions led by Cassidy to areas other than the Yamato Mountains has clearly demonstrated the validity of his thesis.

Statistics on meteorite falls are imperfect, since falls are unpredictable and many go unobserved. However, extrapolation from observations in densely populated regions indicate an average meteorite infall of one per million square kilometers per year, or about 500 a year for the entire planet. Since the oceans cover about 70 percent of the earth's surface, only about 150 meteorites a year fall on land and can be recovered. Because much

of the earth is sparsely populated and recovery is difficult in forested or rocky terrain, the recovery rate is only about ten per year. Statistically, over a period of a million years, there should be one meteorite in each square kilometer. But in the Antarctic, areas of concentration, containing many more meteorites than statistically predicted, are found. The Antarctic icecap evidently functions as a collecting and concentrating medium.

What peculiar features of the Antarctic continent produce these unique concentrations of meteorites? The icecap has existed for millions of years —possibly since the Miocene, some twenty million years ago. Meteorites have fallen on the icecap throughout this period and have been buried in the ice, which moves slowly toward the coast. Much of the ice eventually reaches the coast and either melts or drifts away in the form of icebergs. In some places, however, the ice flow is blocked by mountain ranges. The ice stagnates and is slowly removed by ablation, that is, by evaporation and wind erosion, but is constantly replaced by newer ice from the interior. Solid objects within the ice, the meteorites for example, will remain on the surface and accumulate as a unique form of "lag gravel." It should be realized that much of Antarctica is essentially a dry desert, in which ablation greatly exceeds the accumulation of new snow.

This scenario accounts for the areas of meteorite concentration in association with mountain ranges that block the flow of the inland ice. If the Antarctic icecap has existed for twenty

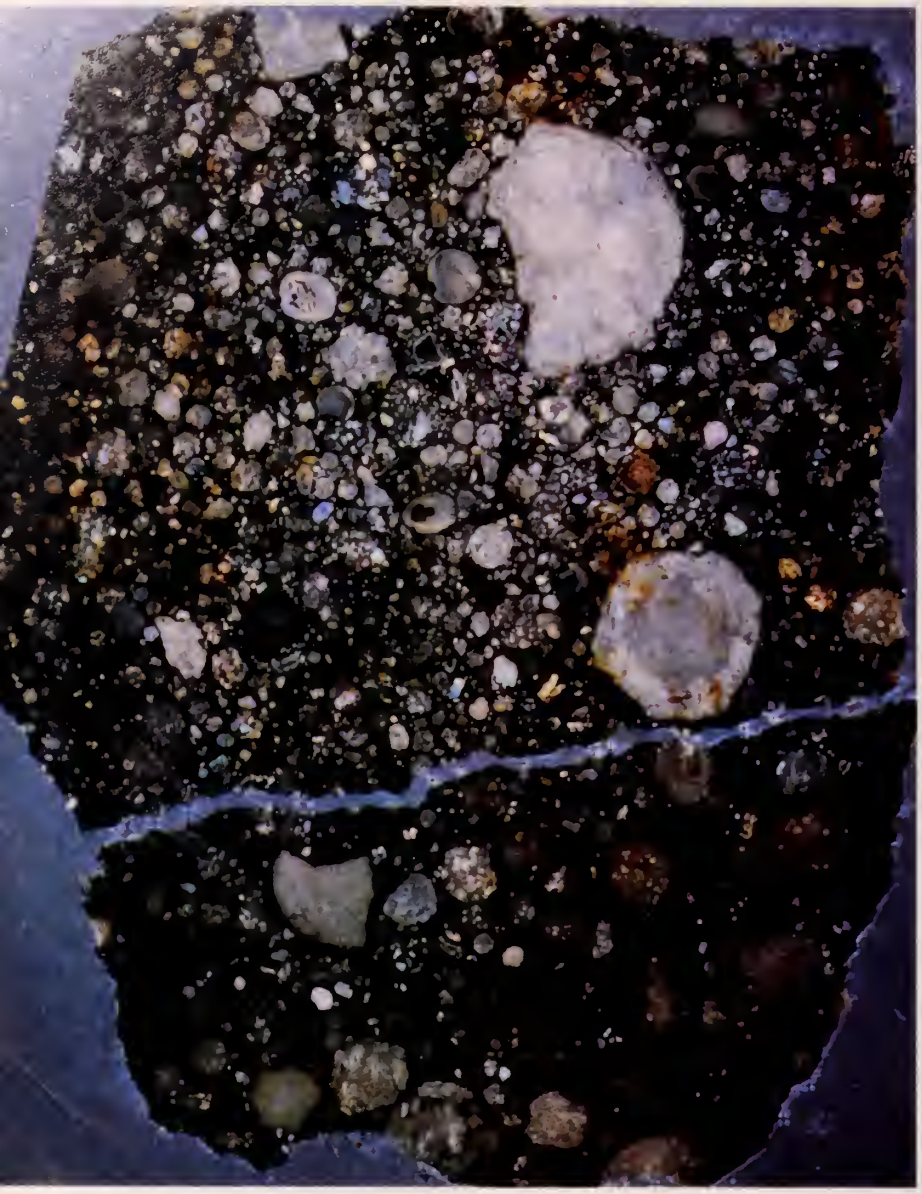
William A Cassidy

million years, there is the possibility of recovering meteorites that have fallen over a very long period of time. (Meteorites falling in temperate and tropical areas are likely to disappear within a few thousand years because of weathering, erosion, or burial.) The Antarctic meteorites fell into the equivalent of a "deep freeze" and have thus been preserved with a minimum of terrestrial alteration and contamination. Given this unique concentration of meteorites, there is a good chance of finding rare or previously undescribed meteorite types.



How long have the Antarctic meteorites been on the earth? What are their terrestrial ages? Conceivably we may expect any age from the present back to the time of inception of the icecap, perhaps twenty million years ago. Meteorites carry within them a time clock in the form of radioactive isotopes produced by cosmic-ray bombardment in outer space. When meteorites land on the earth, this cosmic-ray bombardment is effectively terminated, and the induced radioactivity decays as a function of time. Approximate terrestrial ages have been measured for twenty-seven Antarctic meteorites, and the calculations range up to 700,000 years. This range includes the oldest terrestrial ages ever measured on stony meteorites.

The old terrestrial ages of the Antarctic meteorites have introduced a new and exciting possibility, that of using meteorites as time probes. Measurement of radioactivity induced by cosmic rays should make it possible to span a range of terrestrial ages extending back twenty million years to the time of the inception of the Antarctic icecap. The concentrations of meteorites now being found near the margins of the icecap may well yield specimens old enough to provide critical information on the formation, expansion, and flow directions of the great mass of ice blanketing the Antarctic continent.

One of the unanswered questions that has troubled meteoriticists is whether the meteorites collected and described over the past two centuries are representative of the total influx of meteorites. Are there meteorite types that have escaped recognition and collection? Has the range of meteorite types changed during geologic time? The Antarctic meteorites provide some clues to answering these questions.

The specimens so far classified from the Antarctic collections are: 87 percent chondrites; 5 percent achondrites; 7 percent irons; and 1 percent stony irons. These percentages agree remarkably well with those for all recorded meteorite falls. For the 809 confirmed falls recorded worldwide up to 1977 these percentages pertain: 85 percent chondrites; 8 percent achondrites; 6 percent irons; and 1 percent stony irons. Thus the Antarctic collections appear to be a representative sampling of the terrestrial meteorite influx. A point of interest is that iron meteorites are present in their statistical proportion. It might be expected that because of the great difference in density between nickel-iron and ice, irons would sink to the bottom of the icecap, never to resurface.

Martin Prinz, AMNH

Right: A thin section through an achondrite shows no chondrules. This meteorite looks like certain kinds of terrestrial igneous rocks.

Institute of Meteoritics, University of New Mexico

Because of their pristine condition and scientific value, Antarctic meteorites are handled with the same care that is given to lunar rocks. Beginning with the 1977–78 field season, the following procedures have been followed. After being photographed in place, the meteorites are wrapped in Teflon bags, sealed with tape, and packed in sterile, padded metal boxes provided by the Johnson Space Center in Houston. The boxes are flown to McMurdo Station and then shipped refrigerated to the Space Center, where they are unpacked and the meteorites are placed in a cold storage room at −40°C. Each bag, containing one or more meteorites, is transferred from the storage room to the processing laboratory, where every meteorite is compared to its field photograph to confirm its identity. Each meteorite is then rephotographed (usually from several angles) and weighed; its external features are described; a chip is taken for thin sectioning and petrographic description; and a permanent number is assigned. Once they have been documented, the meteorites are sent to researchers according to the procedures previously established for lunar rocks. As soon as possible after receipt at the Space Center, a piece of each meteorite is sent to the Smithsonian Institution in Washington, where I am responsible for the initial description, classification, and publication of the descriptions.

Meteorites are normally named for the geographical feature (town, river, mountain, and so forth) nearest to their place of discovery. This procedure, however, is clearly impractical for large concentrations of meteorites found in small areas, and a name-and-number combination has been adopted. This combination is a three-letter abbreviation for the locality (for example, ALH for Allan Hills); a letter for the field party (A for the first party, B for the second, and so on); two digits for the year of the field season (77 for the 1977–78 season); and a three-digit number that identifies the individual specimen. Thus specimens collected by the first field party at Allan Hills during the 1977–78 season are numbered from ALHA77001 through ALHA77307.

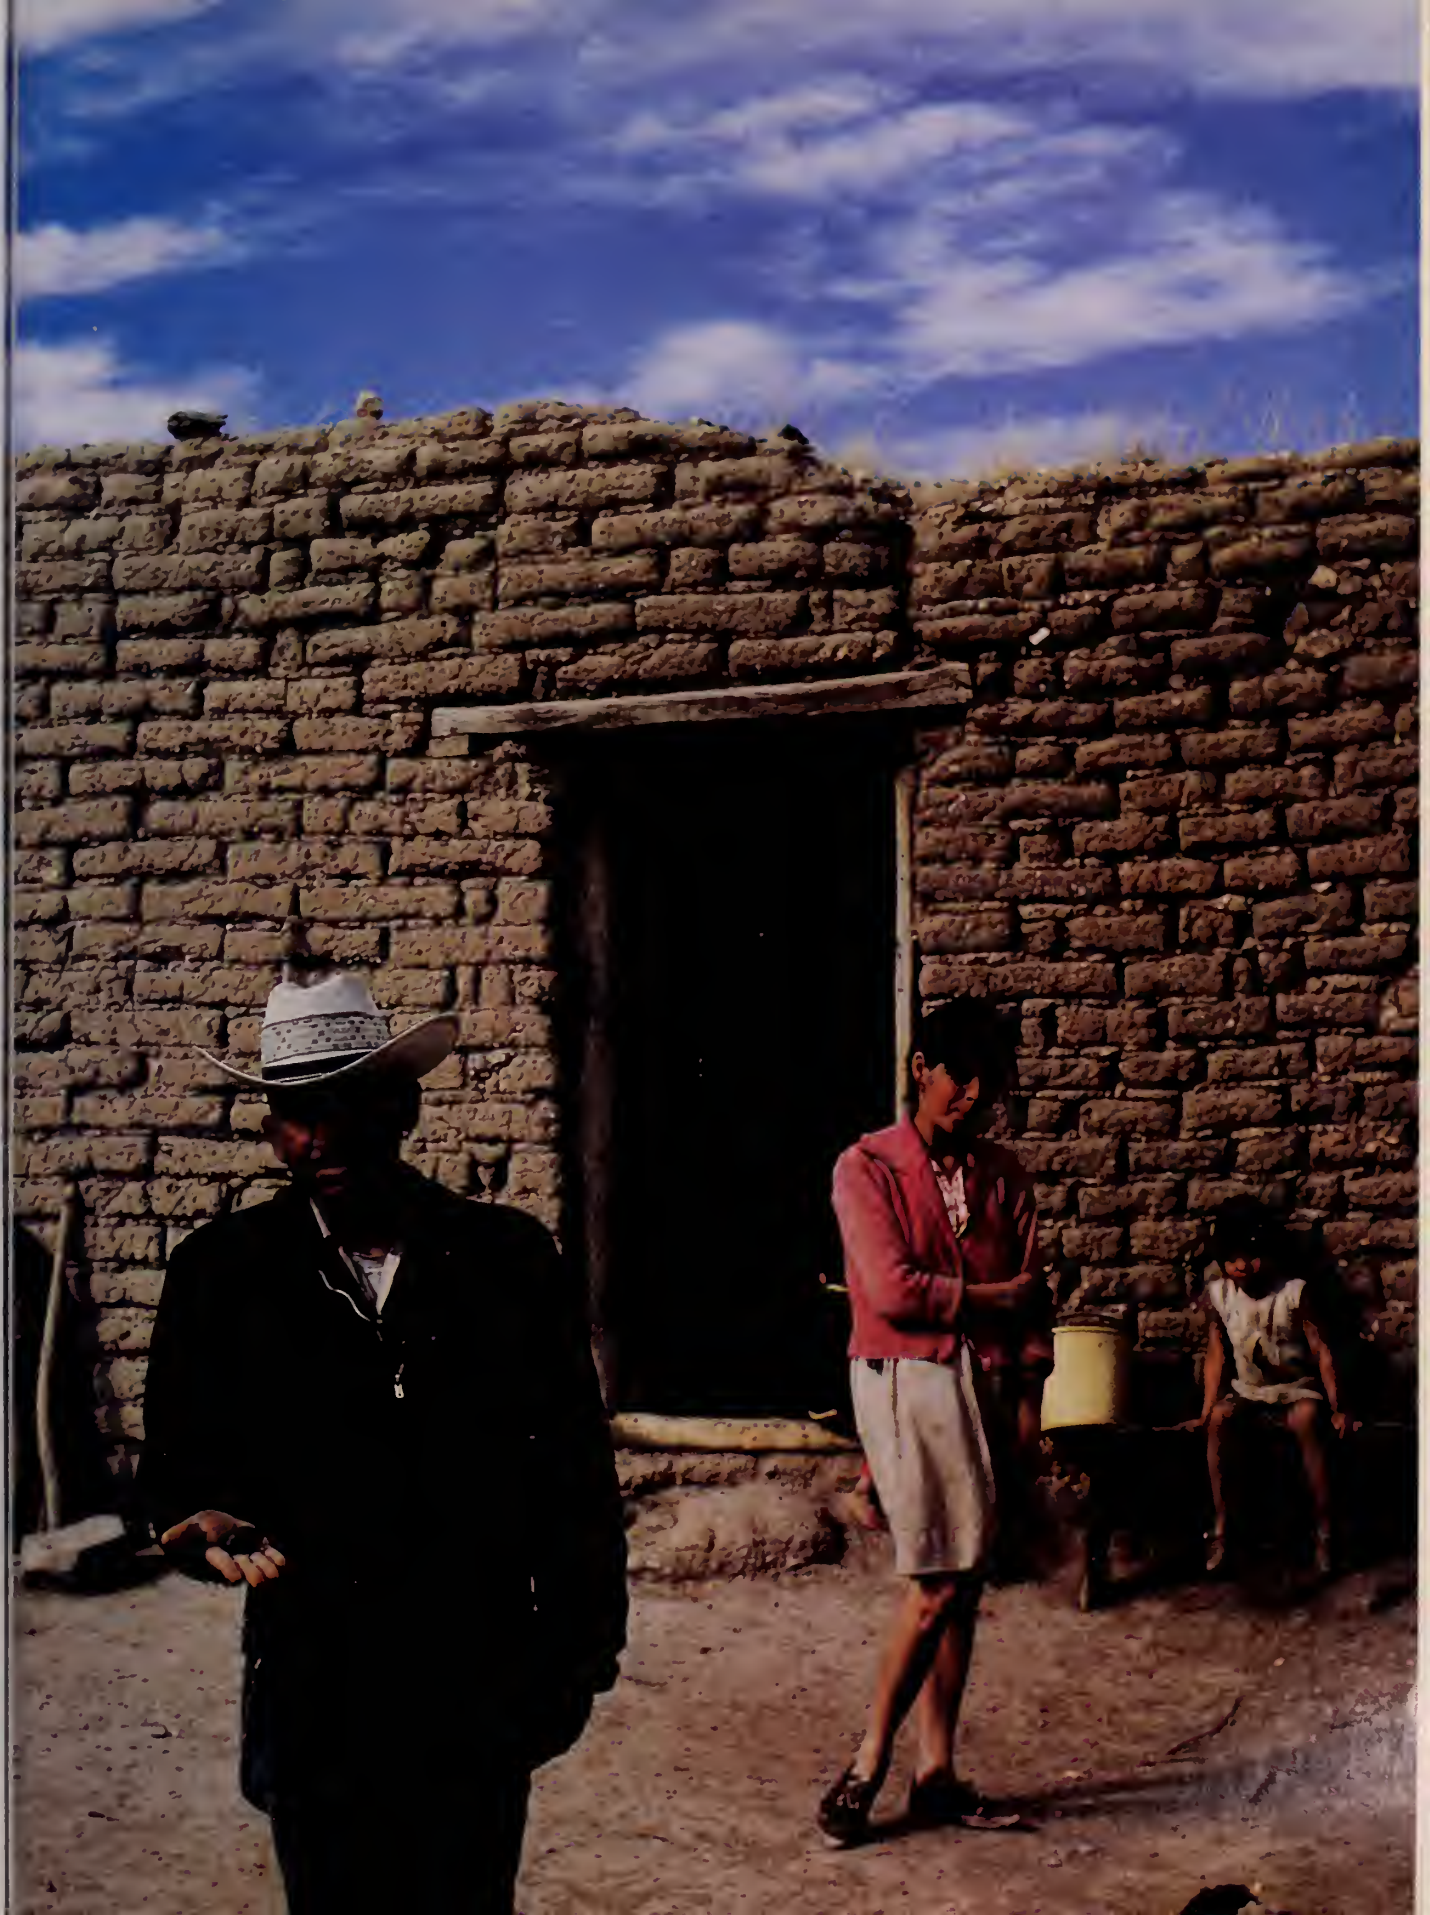
Meteorites have been aptly described as the poor man's space probes —extraterrestrial materials arriving cost-free from outer space and carrying within them a history, albeit imperfectly preserved and difficult to decipher, of events in the universe over the past five billion years. The discovery of the Antarctic meteorites provided a large supply of unique research materials at a propitious time —when a large number of laboratories and scientists experienced in the investigation of lunar rocks were ready and anxious to extend their research to other extraterrestrial material. A fruitful cooperation among specialists in Antarctic meteorites, specialists in lunar rocks, and those studying other planetary bodies has been established, and concurrent investigations of these materials are providing comparative studies of wide-ranging importance for our comprehension of the origin and evolution of the solar system. □

Telltale Inclusions

Mineral grains in the Allende meteorite are studied in order to understand the transition from a cosmic gas cloud to the early solar system

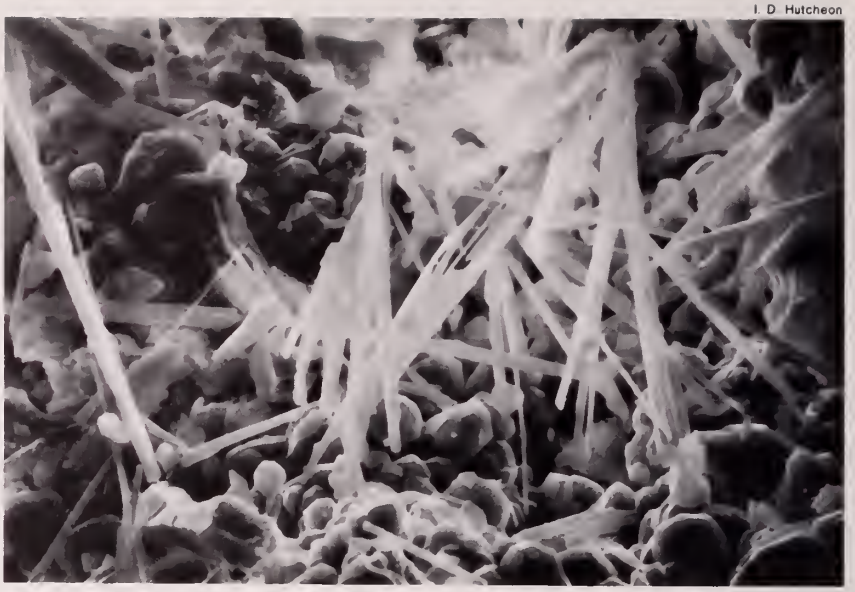
by Lawrence Grossman

Scientists have long recognized that a record of events that occurred at the very beginning of the solar system is preserved in the carbonaceous chondrite meteorites because these objects miraculously escaped later processes, such as vulcanism, that would have erased this information. During the 1960s, the supposition was that these extraterrestrial samples were composed of the very mineral grains that condensed from the solar nebula, the hot gas cloud postulated to have given birth to the sun and the planets. Direct evidence was difficult to obtain, however, as existing specimens of these precious meteorites were considered too small for the extensive studies necessary to test the hypothesis. This barrier was broken suddenly on February 8, 1969, when thousands of pieces of a meteorite fell over a large rural area in the valley of el Rio del Valle de Allende in northern Mexico, providing scientists with four tons of material from a single carbonaceous chondrite. So much material became available that chunks weighing several kilograms were sliced up like loaves of bread. The slicing revealed for the first time that some types of carbonaceous chondrites are heterogeneous mixtures of different types of inclusions, many of which are large enough to be individually sampled and analyzed by several different techniques. I will concentrate here on the wealth of information that was obtained by using these techniques on the coarse-grained, calcium-rich inclusions that constitute about 5 percent of the Allende meteorite.



The elements are made in nuclear reactions in the stars. Different elements and different isotopes of the same element are produced in different stars; yet all stable isotopes are found in the solar system. The nuclear products of the stars are ejected into the interstellar medium where they mix together in enormous clouds. In 1969, the prevailing view among cosmochemists was that the solar system formed when such an interstellar cloud of gas and dust underwent gravitational collapse and fragmentation and when one of the fragments continued to collapse into a disk-shaped cloud called the solar nebula. It was thought that during the collapse, gas mixing was thorough enough to erase any preexisting spatial variations in elemental and isotopic composition and that temperatures were high enough in the center of the nebula to evaporate all preexisting interstellar grains. Outer parts of the disk remained cold. The planets in the inner solar system—Mercury, Venus, Earth and its moon, and Mars—were viewed as having accreted from solid materials that condensed in the inner part of the solar nebula when the gas cooled off again. Hence, what minerals condense from a cooling gas of solar composition and in what order are questions of obvious importance to understanding the chemical compositions of the terrestrial planets.

Controlled condensation experiments are difficult to perform at the high temperatures relevant to this problem, but calculations based on the relative stabilities of minerals and gaseous molecules allow detailed predictions that form the basis for discussion of this subject. These models assume that chemical equilibrium was achieved during condensation. (Chemical equilibrium means the tendency of the minerals and gas present at any given time to become as stable as possible.) The models require thermodynamic data for chemical species that can exist in such a system, as well as estimates of the abundances of the elements in the solar system and of pressures and temperatures in the inner solar nebula. Early versions of such calculations predicted that minerals rich in aluminum, calcium, and titanium would be the first-appearing condensates of any of the abundant elements in a cooling gas of solar composition. In 1972, I predicted the sequence in which various minerals would condense under conditions of complete chemical equilibrium.



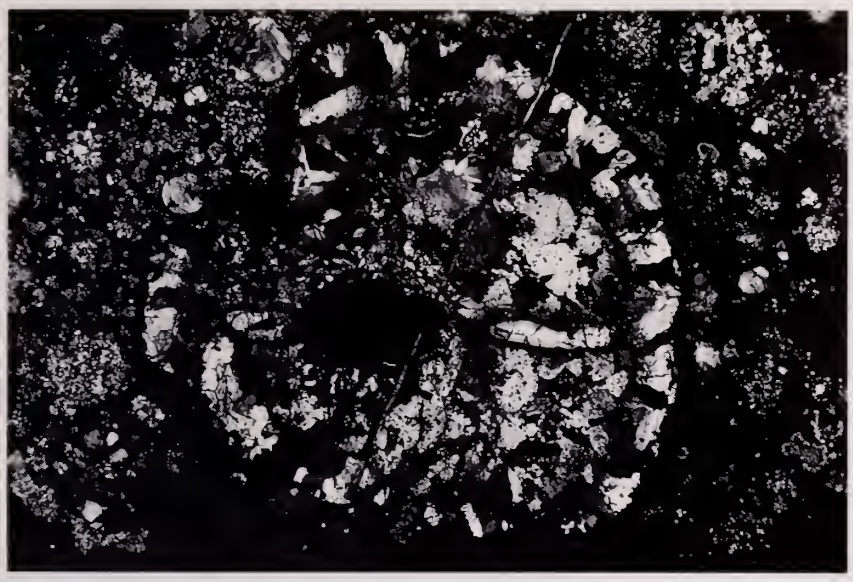
A slab surface of the Allende meteorite shows that the coarse-grained inclusions are prominent because of their large size and light color. Before long, these objects had attracted the attention of the earliest investigators of the meteorite, who discovered that the white inclusions are filled with calcium-, aluminum-, and titanium-rich minerals. The investigators pro-

A piece of the Allende meteorite is exhibited by its finder on February 16, 1969, eight days after the carbonaceous chondrite fell. This photograph was taken in the town of Torreon de Mata, near the southern end of the large area over which the fragments of the meteorite fell.

Roy S. Clarke, Jr.

I. D. Hutcheon

Two types of coarse-grained inclusions—type A and type B—with different mineralogical compositions have been found in the Allende meteorite. Type A, shown here in a scanning electron micrograph, is irregularly shaped. These inclusions may be aggregates of the original solids that condensed from the solar nebula.



posed, on the basis of this similarity to the minerals that thermodynamic calculations predicted would be the first to condense from a cooling gas of solar composition, that these white inclusions must be high-temperature condensates from the solar nebula.

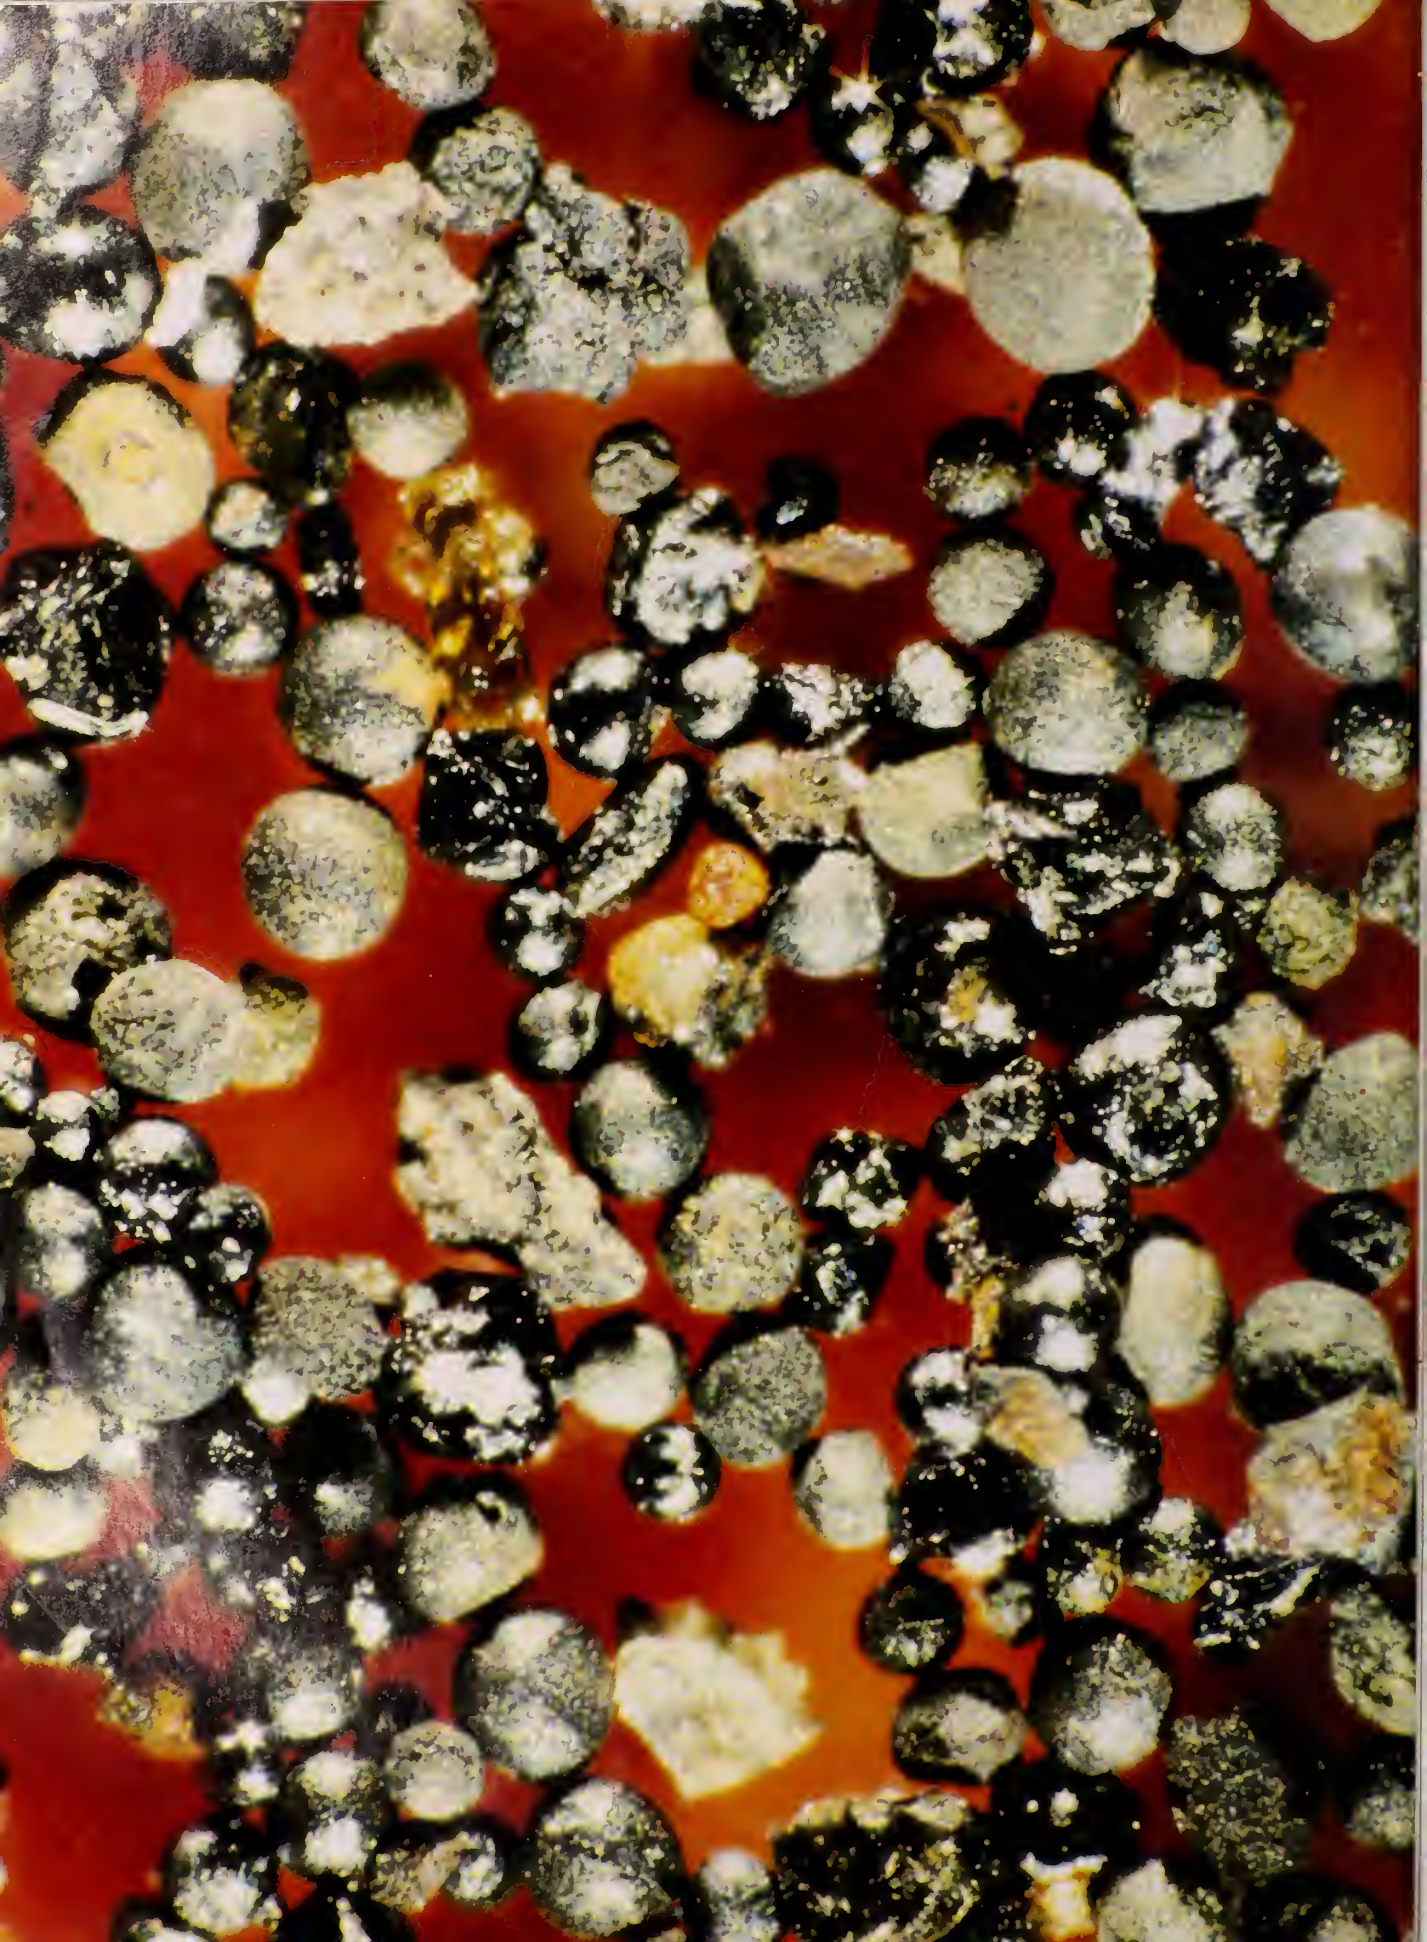
To study the mineralogy of the inclusions, meteorite pieces containing them are sliced into sections so thin that light passes through. The minerals are then identified by their characteristic colors in a polarizing microscope and analyzed chemically by bombarding the polished surfaces of the sections with electrons. Two kinds of coarse-grained inclusions—type A and type B—with different mineralogical compositions exist. In 1972, I pointed out that, except for one mineral, hibonite, the mineralogical composition of the type A inclusions is precisely the mineral assemblage predicted to be in complete chemical equilibrium with a gas of solar composition in the temperature range 1,175°C to 1,250°C at a total pressure of one-thousandth of an atmosphere, conditions thought to be representative of the inner solar nebula. No thermodynamic data exist for hibonite but it was thought to have condensed first, instead of the mineral corundum predicted by the calculations. Many type A inclusions are irregularly shaped and suggest that, while floating freely in the solar nebula prior to incorporation into the meteorite, they resembled "fluff balls," just what would be expected when small particles strike one another and stick together.

In contrast to fluffy type A inclusions, the type Bs are often nearly spherical, the shape that would be taken by a suspended liquid droplet, and their mineralogical composition is different from the type As. Their coarse crystals are tightly intergrown, a texture typical of materials that crystallized from melts. Some possess outer mantles of the mineral gehlenite, in which it can be shown that the crystals grew from the outer margins of the inclusions inward with falling temperature. This can be readily explained if such inclusions were once molten droplets that cooled and solidified from the outside in by radiating heat away from their surfaces. On the other hand, such inclusions cannot be explained by the condensation of solids from a vapor like the solar nebula, as it is very difficult to see why this would lead to formation of a hollow spherical shell of gehlenite that was filled in by later condensates. Thus, it appears that fluffy type A inclusions could be aggregates of the original solids that condensed from the solar nebula, while many type B inclusions melted either during or after condensation.

Further evidence that both types of coarse-grained inclusions are high-temperature condensates comes from their chemical compositions. Sufficient material can be dug from a single inclusion that it can be analyzed for a large number of elements present in major or trace amounts by a technique known as neutron activation. This technique involves the conversion of stable isotopes into radioactive ones by bombarding the sample with neutrons in a nuclear reactor and then determining the concentrations of elements from the amounts of gamma rays emitted at different energies. Such experiments show that a large number of elements that exhibit a wide range of chemical properties are enriched by the same amount (a factor of 17.5) in the inclusions relative to their abundances in an average sample of solar system matter. Condensation calculations show that the chemically diverse elements analyzed by neutron activation share one characteristic: they all condense from a gas of solar composition above or within the range of condensation temperatures of the major minerals in the inclusions. It must therefore be this common feature that enriched all of these elements to the same degree in the inclusions. Although all refractory elements separated themselves from the rest of solar system matter by forming the inclusions, the fact that the enrichment factors for all these elements are the same indicates that they did not separate from one another in the condensation process.

When viewed in thin section with a polarizing microscope, most inclusions contain dark regions. These areas are filled with many crystals so small that they cannot be resolved under ordinary magnification. This dark material tends to fill veins that crosscut gehlenite crystals, indicating that it formed after the gehlenite. The same dark material also fills cavities on the edges of the gehlenite crystals, suggesting that the material in the

Type B inclusions, as this example photographed with a light microscope shows, are nearly spherical. Their shape and tightly interlocking grains suggest that they were once molten droplets. The mineral around the edges here is gehlenite. Other smaller inclusions are visible in the surrounding matrix.



R. S Kjarval

cavities corroded and formed by chemical reaction at the expense of the gehlenite. In order to study the material of the cavities more closely, photographs were taken with a scanning electron microscope and the minerals of that material were identified from the energies of the X-rays emitted by them under electron bombardment. The minerals in the veins and cavities form beautiful, well-developed, multifaced crystals with large amounts of empty space between them. Textures with such empty spaces are usually interpreted as implying crystallization in a gas pocket, a process in which the solid products occupy only a small fraction of the volume of the starting vapor. Although the minerals of these veins and cavities formed by reaction of a previously condensed gehlenite with a gas, none of them are predicted by thermodynamic calculations to condense from a gas of solar composition. One possibility is that the solar nebula differed in chemical composition from place to place and that the Allende inclusions condensed in one region of solar composition but were altered in another area of different composition.

Another indication that the history of the coarse-grained inclusions did not end with the condensation of the major minerals in their interiors is the presence of rim layers around the outsides of these inclusions. Every inclusion is surrounded by the same sequence of four mineralogically distinct rims, each of which is so narrow (three to thirty microns) that a scanning electron microscope is required for its adequate study. The innermost zone is made of typical high-temperature condensates, but the next layer is rich in one of the alteration minerals seen in the veins and that was formed by reaction between the previously condensed minerals and the surrounding nebula. The third layer from the interior of the inclusion consists of another alteration mineral that grades outward in composition to another mineral formed by later condensation. The outermost layer is made of two minerals rich in iron oxide.

The rims have several noteworthy features. Because they are not granular, they cannot have formed by the accretion of grains that crystallized elsewhere, as in sedimentary rocks. Rather, their structure suggests that they crystallized in situ, perhaps by reaction between inclusion interiors and some other material. This reacting material cannot have been minerals in the meteorite matrix in which the inclusions are embedded. The reason is that such a reaction would produce a rim all the way around each inclusion, but sometimes the rims extend only part way around an inclusion even though the matrix completely surrounds the inclusion. Rimming must have occurred prior to the incorporation of the inclusions into the meteorite's parent body, but some rims were broken off between these two events. The rims probably formed in a reaction between the inclusions and the gas of the solar nebula, but some of the reaction products cannot form at chemical equilibrium in a gas of solar composition. Thus, there is once again the possibility that the inclusions were formed in a region of nonsolar composition. The presence of iron oxides in some rim minerals indicates that this region was much more oxidizing than the one from which the interiors of the inclusions condensed because, in it, we know metallic iron was the stable iron-bearing mineral.

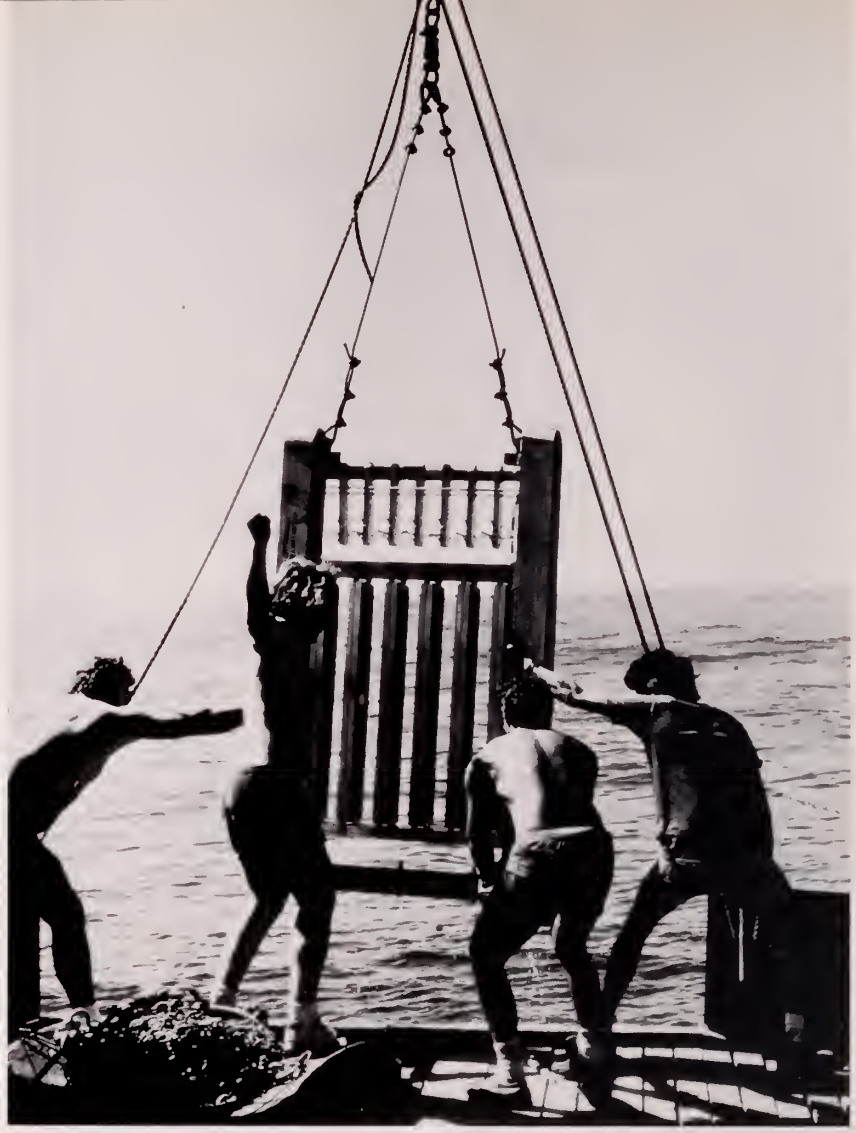
In conclusion, we have seen that the Allende meteorite contains objects that crystallized in the cosmic cloud from which the solar system formed. Some are aggregates of mineral grains that condensed directly from the gas of that cloud. These inclusions are our best clues to conditions and processes that occurred in that distant era before the planets formed. Recorded in the inclusions is a rather complex history of successive condensation events and evidence that the cloud was heterogeneous in chemical composition. Data show that the cloud was also isotopically heterogeneous and that collapse of the interstellar cloud to form the solar system may have been triggered by the explosion of a nearby supernova. It seems likely that the inferred spatial heterogeneity of chemical and isotopic composition of the nebula was caused by last-minute injection into the nebula of supernova matter of different composition. Different parts of individual inclusions appear to have reacted with gases of different chemical and isotopic composition, apparently reflecting the fact that the inclusions began forming before newly injected material was thoroughly stirred with the older matter. □

Cosmic Dust

Interplanetary dust particles from comets and asteroids fall by the ton on the earth, where they can be collected and studied

by Donald E. Brownlee

Meteorites can often be found on Antarctic blue-ice fields and near certain large meteorite impact craters after only a few hours of searching, but finding them elsewhere on Earth is an extraordinarily rare experience. Only about a dozen newly fallen meteorites are found each year by the entire global population of four billion people. This apparent rarity, however, applies only to extraterrestrial materials large enough to be noticed with the naked eye. Small cosmic particles as fine as dust are actually very common, and although invisible to the unaided eye they are present everywhere in our daily environment. Each year more than 10,000 tons of extraterrestrial particles smaller than one millimeter in diameter enter the atmosphere and fall to the surface of the earth. For particles of ten-micron size (a micron is 0.001 millimeter, or about one-sixth the diameter of a fine human hair), the flux hitting the earth's surface is one per square meter per day. If you spend an appreciable amount of time outdoors, you will be "hit" by several cosmic particles a week. However, with fall speeds of a centimeter per second and masses of a billionth of a gram, impacts are less than noticeable. These particles are in the air we breathe, the food we eat, and the water we drink. They are ancient, primitive materials that formed during the earliest history of the planetary system and were stored inside comets and asteroids for most of the age of the solar system—about 4.5 billion years.



Some of the dust particles are fragments of larger objects that broke up while entering the earth's atmosphere, but the majority are believed to have been small particles of interplanetary dust out in space. Interplanetary dust is material that orbits the sun, forming a giant, flattened cloud centered on the ecliptic—the orbital plane of the planets. This cloud can be seen in the night sky as a faint glow extending along the ecliptic and fading with increasing distance from the sun. The glow is caused by light from the sun scattered off the zodiacal cloud: the vast cloud of dust particles one-micron to one-millimeter in diameter that exists in the solar system.

The interplanetary dust particles that are currently falling into the earth's atmosphere had only a brief existence as small particles in space. Prior to that they were stored inside larger "parent bodies." In almost all cases the parent bodies are comets and asteroids, dusty objects without permanent atmospheres and with low surface gravities. The dust must be generated on a semicontinuous basis because the zodiacal cloud is long-lived in spite of the fact that individual particles are disintegrated by high-velocity collisions with one another on time scales of only 10,000 to 100,000 years. Comets are believed to be the major source of the dust since they are the dominant place of origin of the millimeter-sized particles that produce visible meteors, or shooting stars, in the night sky. From the luminous path of a meteor it is possible to determine the particle's orbital path around the sun, and in most cases the orbits are similar to those of comets. For some annual meteor showers, the meteors can be shown to have originated from specific comets.

All of the cosmic particles on the earth entered the atmosphere at extremely high velocity (greater than twelve kilometers per second) and were subjected to elevated temperatures and, sometimes, extreme mechanical stress as they decelerated. The character of a particle's high-velocity entry into the atmosphere is dependent on its size. Large meteoroids, say larger than ten centimeters, penetrate deeply into the atmosphere at high velocities until they reach altitudes of less than thirty kilometers. There the air density is significant and generates large pressures on the leading edge of the meteoroid, causing its surface to melt and vaporize. Although the surfaces of the big meteoroids melt, their interiors remain cool, much like a baked Alaska. Their interiors may escape strong heating, but the pressures acting on big meteoroids during entry are so great that fragile materials disintegrate and only fairly strong rocks survive intact. This selective process may explain why the majority of recovered meteorites are thought to be asteroid chunks even

Most of the cosmic spheres that accumulate on the sea floor are magnetic, a fortuitous circumstance that facilitates their collection. The spheres in this enlargement were gathered in 1979 in the Pacific Ocean southeast of Hawaii.

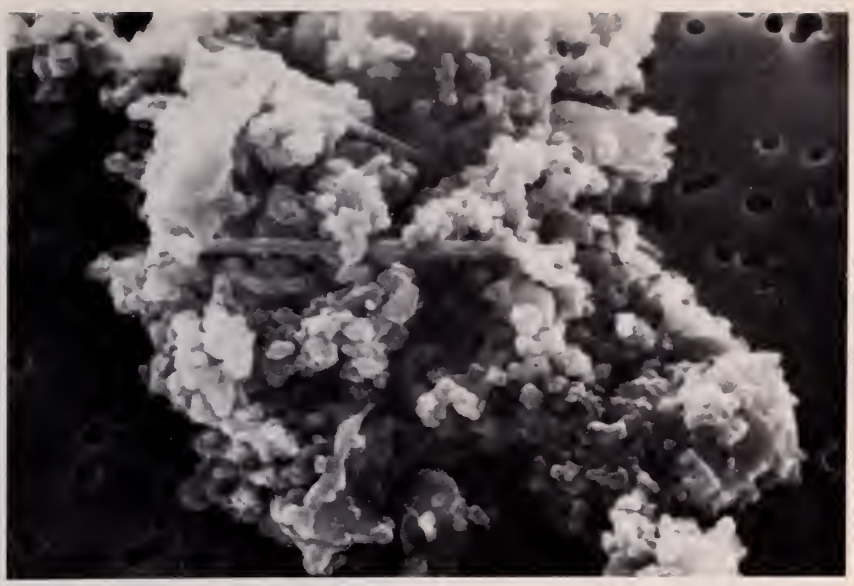
Donald E Brownlee

Cosmic Muck Rake is the nickname for this magnetic contrivance devised by researchers at the University of Washington for the collection of cosmic spheres from the sea floor. The rake is usually towed through the water at depths of about five kilometers, picking up tens of thousands of spheres in a day.

Leo Pilachowski

though most meteoroids in space are believed to be of cometary origin and are probably composed of weak and fragile materials.

Fortunately, the strength problem, or the ability of materials to resist pressure, is less severe for dust particles than for large meteoroids. Small particles of less than 100 microns in diameter decelerate from their cosmic velocity of about fifteen kilometers per second high in the atmosphere to speeds of about one centimeter per second near altitudes of one hundred kilometers. There the air is so thin that the maximum pressure generated on the particles is a thousand times smaller than the pressure experienced by bigger objects lower in the atmosphere. The fact that many of the extraterrestrial dust particles that have been collected are more porous and fragile than conventional meteorites is proof that the strength problem is not severe for cosmic dust.



The heating of interplanetary dust as it enters the atmosphere is also a function of size. Most of the particles smaller than fifty microns decelerate in very thin air where the rate of frictional heating is so low that the particles are not heated to their melting points. Dust particles that survive entry without any melting are called "micrometeorites," as defined in the 1950s by the American astronomer Fred Whipple. Most of the particles larger than 100 microns do not slow down until they reach high enough air densities to cause melting. Big particles larger than a few millimeters can have fairly cool interiors even though their exteriors melt, but as they melt, surface tension pulls them into the shape of spheres, and they solidify within a time span of seconds and at very high altitudes. Some rare particles larger than 100 microns can escape melting only if they enter the atmosphere at an oblique angle.

To investigate the true physical nature of interplanetary dust, it is an enormous advantage to capture individual particles that can then be studied in the laboratory. Space would seem to be the obvious place to collect interplanetary dust. Unfortunately, this is impossible to do in a nondestructive way because of the enormously high velocity of the particles relative to any collector that might be put into space. A cosmic dust particle striking a spacecraft decelerates from a velocity of fifteen kilometers per second to zero in only a billionth of a second. The impact vaporizes the particle and a tiny crater (and possibly some debris) is the only remaining evidence that the particle ever existed. With this problem in mind, it is clear that the earth itself is perhaps the ideal cosmic dust collector. In the thin air of the upper atmosphere, incoming particles are decelerated relatively gently, and the "collision" with the earth's atmosphere can be nondestructive.

The problem with the earth is that while it is a good cosmic dust catcher, the actual recovery of individual dust samples for laboratory study is very difficult. Paradoxically, although extraterrestrial dust is everywhere around us in our terrestrial environment, it is almost impossible to find. The situation is different for large meteorites, of course. If a 100-kilogram meteorite fell today in New York City it would almost certainly be found since large rocks falling out of the sky are unusual and conspicuous objects. This is not the case for ten-micron cosmic dust particles. While it is true that on the average a square meter of New York will collect one cosmic dust particle every day, it will also collect up to ten billion other par-

A scanning electron micrograph of a stratospheric dust particle shows that it is composed of large numbers of submicron grains. Particles such as this, collected with a U2 aircraft, are thought to be the most common type of interplanetary dust.

Donald E Brownlee

ticles of similar size. In an optical microscope, the cosmic particles are indistinguishable from the terrestrial particles. In an electron microscope, the chemical compositions of individual particles can be determined, making it possible in principle to identify the single extraterrestrial particle among ten billion contaminants, but in practice that would take centuries of work.

Fortunately, there are better places than cities in which to collect extraterrestrial dust. Two regions where cosmic dust particles can be successfully collected are the stratosphere and the deep-ocean floor. In the stratosphere, at altitudes above twenty kilometers, "large" terrestrial particles are quite rare and most particles bigger than ten microns are not particles that rose from the earth's surface but ones that fell in from space. Large terrestrial particles are scarce in the stratosphere because they are only lifted to high altitudes by such rare events as huge thunderstorms or volcanic explosions, and because of their relatively high fall speeds (a kilometer a day).

The other good collecting locality for extraterrestrial dust is the deep-ocean floor in regions far from continents and islands. The ocean floor may be one of the dirtiest environments on the earth, but it is a place uniquely suited for the recovery of extraterrestrial material. Although cosmic particles that fall onto the sea floor are greatly diluted with terrestrial materials, they are less diluted than those recovered anywhere else on Earth. In the center of the Pacific Ocean, the accumulation of sediments from the continents, for example, is only a few meters in a million years. A cubic meter of sea-floor mud, then, contains all of the extraterrestrial particles that fall onto a square meter of surface area in a period of nearly 500,000 years. The long accumulation time of deep-sea sediments makes it possible to obtain samples of much rarer and therefore much larger particles than can be collected in the stratosphere.

The "trick" in collecting cosmic material from deep-sea sediments is that most of the extraterrestrial particles in the 0.1 millimeter to 1 millimeter size range are magnetic, a property that distinguishes them from nearly all other particles of similar size on the sea floor. The magnetic mineral magnetite forms in most meteoritic materials that are melted or heated to high temperatures in the atmosphere. For example, the fusion crusts of stony meteorites are magnetic even though their unmelted interiors may be nonmagnetic. Because of their magnetic property, the larger dust particles can be easily extracted from deep-sea sediments by means of simple magnets.

The first positively identified extraterrestrial particles collected in the atmosphere were obtained in 1970 with a University of Washington high-altitude balloon experiment called the Vacuum Monster. At the present time, particles are routinely collected in the stratosphere with NASA U2 aircraft flown from Ames Research Center in California. The U2 carries a small pylon underneath its wing that exposes a sticky flyswatter-sized collection plate to the airstream. After exposure on ten or fifteen consecutive flights the collection plate is removed to a clean room, where individual particles are picked off with tiny glass needles and mounted for study in analytical electron microscopes and other instruments.

The extraterrestrial particles are a fairly large fraction of all the collected particles larger than a few microns and identification is not usually a problem. Most of the cosmic particles have elemental compositions similar to primitive meteorites and are distinctly different from nearly all terrestrial contaminants. The most common contaminants are pure aluminum oxide (sapphire) spheres, which are the combustion products of solid fuel rockets. The proof that the particles identified as cosmic are indeed extraterrestrial came from the detection of helium and other rare gases implanted in them by the solar wind. The rare-gas content is high, comparable to that in lunar soil, and is undoubtedly the result of implantation of the ions composing the solar wind while the particles were in space.

Most of the 500 extraterrestrial particles that have been collected in the stratosphere are true micrometeorites —dust particles that have survived entry into the atmosphere without melting. They are small, less than fifty microns in diameter, exceedingly rare, and difficult to collect. The collection of a single ten-micron particle requires sampling more than a thousand cubic meters of stratospheric air. Particles larger than 100 microns are so rare

In this scanning electronmicrograph, the surface of a stony deep-sea sphere, etched by ocean water, reveals crystals of different minerals.

Donald E Brownlee

that collection of a significant number of them from the atmosphere is beyond our present ability. The way to collect these larger dust particles is not to try to capture them before they hit the ground, but to find some region on the earth where they accumulate over a fairly long period with a minimum of terrestrial contamination. The best such place is the sea floor.

Because of the relative ease of recovery and the durability of large particles in sea-floor sediments, most of the cosmic particles from that source are in the range of fifty microns to a few millimeters. The majority of these particles melted during entry into the atmosphere, forming small round bodies commonly called cosmic spheres. True unmelted micrometeorites must exist in ocean sediments but they are probably not very magnetic, and because of their contact with mud and water, they would be in much less pristine condition than those collected in the atmosphere. The sea floor is the best collection site for large melted cosmic spheres, but the smaller true micrometeorites are best collected in the stratosphere despite the difficulties involved.

Cosmic deep-sea spheres are highly degraded samples of interplanetary dust that were melted in the atmosphere and later at least partially modified chemically in the ocean. They are valuable because they are relatively large. A one-millimeter sphere contains a million times more mass than a ten-micron particle. The larger size is a great advantage when attempting to measure trace elements in the material or when trying to determine the isotopic composition of stable elements such as oxygen or of radioactive isotopes such as manganese 53, produced by cosmic-ray bombardment in space. Many of the valuable measurements require spheres a millimeter in diameter but spheres of this size are so unusual that only a few can be found in a ton of sediment.

The first cosmic spheres were found more than a century ago when scientists on the British *Challenger* expedition in the 1870s ran a hand magnet though mud samples recovered from the sea floor. They found curious spheres, some of which contained metallic iron. Metallic iron is very rare in nature, and the researchers correctly concluded that the particles were extraterrestrial.

To collect large particles without bringing tons of mud into the laboratory the sensible approach is to do the magnetic separation in situ on the ocean floor. This was first done in the 1950s by Danish oceanographers using magnets mounted in a wooden plank that was dragged along the sea floor at several locations around the world. This technique was recently improved on by University of Washington researchers who used a 300-kilogram magnetic collection device, something like a sled, called the Cosmic Muck Rake. The collection sled was towed in the Pacific Ocean at a depth of 5,300 meters by the University of Hawaii research vessel *Kana Keoki*, and tens of thousands of cosmic spheres, ranging in size up to three millimeters, were collected.

Studies of the deep-sea cosmic spheres made by an international group of investigators have concentrated on elemental and isotopic composition because most of the other properties of these particles were destroyed by melting during atmospheric entry. The compositions of the spheres fall into two basic groups: type I (for iron), composed of metallic iron and magnetite; and type S (for stony), composed of silicates and magnetite. Since the origin of the type I spheres remains unknown, it is not clear whether the parent materials are pure iron meteoroids or stony bodies that contain metallic iron. The elemental compositions of the type S spheres indicate that approximately 80 percent of them are solidified droplets of a material similar in composition to the carbonaceous chondrites but different from the ordinary stony meteorites. This is noteworthy because only 2.5 percent of freshly fallen meteorites that are larger than dust size are of the primitive carbon-rich variety. Apparently, carbonaceous chondritelike objects are more common in space than their scarcity in meteorite collections would suggest. The cosmic spheres are probably a more representative sample of the millimeter-size objects in space than normal meteorites are of the bigger objects. All materials presumably melt and form spheres, but only fairly strong materials become traditional meteorites.

Studies of micrometeorites collected with U2 aircraft reveal detailed information on interplanetary dust because these samples are the least altered by atmospheric entry. Extensive investigation with optical and electron microscopes has shown that the most

This crater in a lunar rock was created by a high-velocity cosmic dust particle striking the moon. The crater was discovered when the rock sample was viewed with a scanning electron microscope.

Donald E Brownlee

common interplanetary dust particles are black aggregates of tiny grains of submicron size, smaller than the wavelength of light. A single ten-micron particle is actually a collection of nearly a million grains ranging in size from several microns down to 100 angstroms or less. (Angstroms are used to measure the wavelengths of light and intermolecular distances. One angstrom equals one ten-thousandth of a micron.) The individual grains are usually iron-magnesium silicates or iron sulfides. Some of the submicron grains themselves are aggregates of carbonaceous materials and tiny crystalline silicates. The bulk elemental compositions of the aggregates are similar to carbon-rich meteorites, yet the structure and to some extent the mineralogy of the particles are different from those of established meteorite types. Many of the particles are fragile, and some are porous, forming weakly bonded structures that resemble bunches of grapes. The material that makes up the most common type of interplanetary dust has not been found in the bigger meteorites, presumably because it cannot survive entry into the earth's atmosphere in large pieces.

In addition to the aggregates of submicron particles, a variety of other types of micrometeorites from the stratosphere have been studied. Some of these particles are single crystals of silicate minerals or iron sulfides that are coated with a thin micropowder of material identical to the fine-grained material that composes the aggregates. These particles were probably embedded in the aggregate material at one time but were broken out either by processes that occurred in space or during atmospheric entry. Other types of particles have more mysterious origins. These types include crystals of metallic nickel-iron, particles composed of carbonates or phosphates, particles composed of stacks of iron-sulfide platelets, and particles composed of glass spheres coated with tiny mounds of metallic nickel-iron.

Laboratory studies of micrometeorites and cosmic deep-sea spheres indicate that most interplanetary dust particles are primitive, complex materials that are often more fragile and porous than meteorites. While the origin of these extraterrestrial particles is not certain, it is probable that they are samples of comet dust. The most porous particles are so fragile that their mere existence may be inconsistent with their ever having been inside a pure rocky body such as an asteroid. If the particles are comet dust, they may be samples of the building materials of the giant outer planets preserved at low temperatures ever since the formation of the solar system. Comets are unique bodies composed of dust and ice that accumulated in the cold outer regions of the primordial solar nebula. The dust contained in comets is expected to be well preserved because comets are cold objects that have never been warm and have spent most of their lifetime at great distances from the sun. The typical solar system comet has a surface temperature only a few tens of degrees above absolute zero and exists so far from the sun that the sun viewed from a comet would be just a small star in the sky, only a little brighter than Sirius, the brightest star visible from the earth.

The truly exciting aspect of comet dust is the possibility that it might be older than the solar system itself. The solar system was formed from interstellar gas and dust; in the cold regions where the comets formed, some ancient presolar system grains may have survived with minimal alteration. The aggregate interplanetary dust particles may be collections of these grains. In that case, the study of interplanetary dust particles may not only give us information about comets and how solid bodies formed in the solar nebula but it may also give us direct, detailed information about environments elsewhere in our Galaxy. The comet dust that falls on you each week may contain a little stardust, perhaps as old as the Galaxy itself. □

Heaven's Habitués

"On the sixteenth of November, 1492, a singular miracle happened: for between eleven and twelve in the forenoon, with a loud crash of thunder and a prolonged noise heard afar off, there fell in the town of Ensisheim a stone weighing 260 pounds. It was seen by a child to strike the ground in a field near the canton called Gisguad, where it made a hole more than five feet deep. It was taken to the church as being a miraculous object. The noise was heard so distinctly at Lucerne, Villing, and many other places, that in each of them it was thought that some houses had fallen. King Maximilian, who was then at Ensisheim, had the stone carried to the castle; after breaking off two pieces, one for the Duke Sigismund of Austria and the other for himself, he . . . ordered that the stone be suspended in the parish church."

From a document in the town archives, Ensisheim, Germany

"The meteorite appeared as a ball of fire in the west September 2, 1905, at ten o'clock in the evening, the sky being cloudless and the clear atmosphere of the plains being undisturbed by wind. From Scott City to Syracuse, 75 miles southwest, it was light enough to read common newspaper print on the street and the explosions rattled doors and windows. The mass exploded, and then the resulting fragments exploded several times in rapid succession. Then came the sounds of the explosions, the whistling like bullets or heavy hail of the smaller fragments and a most intense humming like that of a rapidly revolving cylinder of some heavy machine, evidently caused by the larger mass. This was followed by fierce cannonading (echoes of the explosions?) like the discharge of a battery of artillery or a rapid-fire machine gun, gradually growing fainter and dying out like rolling thunder in the distance. I heard the largest one drop and hunted for it for over two years.

"On May 6, 1908, I was breaking new ground on the prairie with a gang plow and a five-horse team that was a little too high-spirited to be controlled easily, but having half-mile furrows as smooth as a lawn before me, I had set the plow a few notches deeper into the ground and let them go, thinking nothing of meteorites. While congratulating myself upon our speed we suddenly—very suddenly—struck something hard. It threw me out of my seat and piled my gang plow up in a promiscuous heap against the team, which was too badly surprised to do anything. I commenced stabbing with my jackknife and soon located the cause of the disturbance. It was the largest fragment of the Modoc meteorite and completely buried under the tough buffalo sod (virgin soil) and was pounded in so hard that the force of the blow of my gang plow had not loosened it. So completely was it buried, that I had hunted dozens of times all over that pasture without either finding the rock or the hole in the ground which it had made."

J.K. Freed, Modoc, Kansas

"[On October 17, 1921, at 11:00 P.M.] I saw it very light out of doors and heard a roaring sound and then

STAR & SKY HAWAII/ ECLIPSE CRUISE

Sail into the path of totality -in the North Pacific- on July 30, 1981!

On February 26, 1979, millions of Americans watched as the moon's disc covered the sun, producing nature's superspectacular – a total solar eclipse. But the celestial clockwork has ordained that America will not be placed under the moon's shadow again for 36 years. Last year eclipse-chasers travelled to Africa and India to see the spectacle. Since total solar eclipses can be witnessed somewhere on Earth about once a year, we decided to sail into the path of totality in the North Pacific on July 30th.

Be among the special group of people who will view a total solar eclipse from the decks of a 30,000-ton 682-foot luxury liner at sea. ***Star & Sky Expeditions*** has contracted the SS Oceanic Independence, of American registry, for the sole purpose of seeking the awesome darkness at midday.

The 14-day cruise includes the voyage to and from the eclipse site, approximately 1200 miles northwest of Honolulu. ***This location has better than an 80% chance of clear skies – SUBSTANTIALLY BETTER THAN ANY OTHER LOCATION ALONG THE PATH OF TOTALITY.***

The eclipse-viewing will be followed by a ***5-day Hawaiian Island cruise,*** making ports-of-call on the islands of Kauai, Maui, Hawaii, and Oahu.

Our scientific staff is the finest ever assembled for an eclipse cruise: ***Bart Bok,*** formerly professor of physics, Univ. of Ariz., and director, Steward Observatory. ***John Eddy,*** senior scientist, High Altitude Observatory, Boulder, Colo., and solar expert and author. ***William J. Kaufmann,*** adjunct professor of physics, San Diego University, and author of nine books on astronomy and relativity. ***James Sadler,*** head meteorologist, Univ. of Hawaii. ***George Keene,*** senior engineer, Eastman Kodak, and astrophotography expert. ***Terence Dickinson,*** editor, *Star & Sky*. Our cruise director is ***Robert T. Little,*** Field Sales Manager for Criterion Scientific Instruments, veteran of three eclipse cruises and seven Astronomy Island cruises to Bermuda, pioneer of solar-eclipse photography at sea.

Space for this incredible eclipse cruise is limited so you must act now. Prices start at $2,000 per person, double occupancy, plus airfare. Detailed information is available in our brochure which can be obtained, along with a free copy of our 1980 eclipse issue, by writing to:

Star & Sky Expeditions, Inc.

three loud explosions. I thought it was an airship and it was dropping some bombs or something of that character. I jumped up and ran to the door, and the big light was disappearing in the south. The roaring itself was not so very loud, but the explosions were very loud indeed, and while I stood in the doorway watching the disappearing light, I distinctly heard a sound like fine singing."

Mrs. George Hall,
Rose City, Michigan

These three eyewitness accounts of meteorite falls have one thing in common: they all describe meteorites that ended up in the collection of the American Museum of Natural History. Along with hundreds of others— each with a fascinating story to tell—the three meteorite fragments will be on display in the Museum's new Arthur Ross Hall of Meteorites, scheduled to open April 30.

The Museum's meteorite collection, one of the finest in the world, includes pieces from half of all known meteorites. The new permanent hall will exhibit a piece from the oldest documented fall, a meteorite studded with tiny diamonds, microscopic meteorites, hundreds of strange little blobs of glass known as tektites, three moon rocks, and much more.

The largest meteorite in captivity—the second largest known—dominates the center of the octagonal hall. Called the Ahnighito or the Tent, this 62,085-pound chunk of nickel-iron rests on six massive steel pillars embedded in the bedrock beneath the Museum. Flanking the Ahnighito are two lesser companions, the Woman and the Dog. All three are fragments from a 200-ton fireball that exploded over Greenland about 10,000 years ago, scattering its remains across an ice sheet.

The three chunks were discovered, possibly eight centuries ago, by Eskimos, who hammered off pieces of iron to make knives and spears. In 1894 Adm. Robert E. Peary, following up rumors of an "iron mountain," located them with the help of an Eskimo guide. Peary managed to excavate the meteorites, move them from their resting place near Cape York, Greenland, to his ship *The Hope,* and transport them to New York. While Peary was on his way to the North Pole in 1906, Mrs. Peary, acting as his agent, sold them to the Museum. She explained

A block-long team of horses hauled Ahnighito to the Museum in 1906.

her reasons in a letter to Morris K. Jesup, president of the Museum: "The meteorites are all I have and I feel that I should make an effort to turn them into money and invest it so that my children will have something with which they can be educated and fitted to earn their living.... Mrs. Jesup would scold me for bothering you but what can I do?... I have come to the conclusion that it is much easier to go to the Arctic and do the thing you are interested in and want to do than it is to stay at home, bring up the children, fight your husband's battles and look out for bread and butter for the family. I think hereafter I will do the exploring and let Mr. Peary take care of the home life."

After bargaining for several years, Mrs. Peary and the Museum agreed on a price of $40,000. It is interesting to note that, in 1979, moving the three meteorites from the Planetarium to the new hall—a distance of a few hundred yards—cost the Museum more than $100,000.

The new hall is the best of several meteorite halls in the Museum's history, thanks to the generosity of Arthur Ross, a Museum trustee, and the expertise of Martin Prinz, curator of

the hall. "Meteorites," says Prinz, who is also chairman of the Department of Mineral Sciences, "are the Rosetta Stones of the origin of the solar system and planets. In order to understand the planets—including the earth—we have to study meteorites." The hall, Prinz explained, will tell the story of meteorites: Where do they come from? What happens when they hit? What are they made of? What can they tell us about the birth of our solar system?

In the new hall, illustrations, photographs, colorful graphics, and the meteorites themselves will give Museum visitors a dynamic picture of the latest knowledge about these objects from outer space. The power of meteoritic impacts is brought to life on a five-foot video screen; visitors, for example, can watch film footage from the first expedition to investigate

A major symposium, **Meteorites and Planets**, will mark the opening of the Arthur Ross Hall of Meteorites. On Wednesday, April 29, in the Auditorium, leading authorities on meteorites, the planets, and the solar system will discuss their research and the tremendous growth of knowledge about meteorites and the solar system since men first landed on the moon. The Special Supplement in this issue of *Natural History* includes articles by three symposium speakers.

The symposium will be presented at a nontechnical level for the general public. Speakers will consider such questions as: What can meteorites tell us about the origin of the solar system? How do planets form and melt? What happens when meteorites hit? Did they play a role in the extinction of the dinosaurs? What are meteorites made of? The cost of the symposium is $3 for Museum members and students, and $5 for nonmembers. All those attending the symposium will have an opportunity to preview the new hall.

A complete schedule of symposium events appears below:

1:30 P.M. *Introductory Remarks.* Martin Prinz, chairman of the Department of Mineral Sciences; Thomas D. Nicholson, director of the Museum; Arthur Ross, Museum trustee.
1:45 P.M. *The Birth of Planetology.* John Wood, Smithsonian Astrophysical Observatory and Harvard University (see page 56).
2:20 P.M. *Meteorites as Rosetta Stones for Planetology.* Lawrence Grossman, University of Chicago (see page 68).
3:15 P.M. *Meteorites Falling Everywhere.* Donald Brownlee, University of Washington and California Institute of Technology (see page 72).

Jane Goodall Lecture

Celebrated primatologist Jane Goodall will give a lecture at the Museum entitled *The Chimpanzee: Portrait of the Best-known Ape.* Using slides and film, she will discuss her research with the chimpanzee population of the Gombe Stream Reserve in Tanzania. Her project, now in its twentieth year, is one of the longest continuous studies of a wild animal population ever undertaken. Goodall has witnessed family quarrels, reconciliations, the rise of dominant males, and the splintering of a chimpanzee community. *The Chimpanzee* is being presented by the Membership Office on Wednesday, May 13, at 7:30 P.M. in the Auditorium. Tickets cost $4.50 for members, $7.50 for nonmembers. Associate members may order one ticket at the members' price; participating and donor members may order up to four. Send checks to Jane Goodall Lecture, Membership Office.

Asian Dance

Modern and traditional dances of China, Japan, the Philippines, Tahiti, and other Far Eastern cultures will be presented by the Asian-American Dance Theater. This free Education Department program will take place in the Auditorium on Sunday, April 5, at 2:00 P.M.

Alvin Ailey Repertory Ensemble

The acclaimed Alvin Ailey Repertory Ensemble will give a free dance concert in the Museum Auditorium on Wednesday, April 15, at 7:30 P.M. The concert is sponsored by the Education Department and free tickets will be distributed beginning at 5:30 P.M. at the first-floor Information Desk.

the Tunguska explosion that devastated the Siberian landscape in 1908.

"Meteorites are at the heart of many questions about the planets, the solar system, and even life on Earth," says Prinz. "We hope to look at these questions in a dynamic and interesting way, reflecting the tremendous growth in our knowledge since men landed on the moon in 1969."

Douglas J. Preston

Native American Verse

A reading of Native American poetry will be held on Wednesday, April 29, at 7:00 P.M. in the People Center. This free event is part of a three-program series entitled *Version of the Traditional*, arranged by the Education Department.

To the Raptors

The April membership program, *Birds of Prey*, will look at the raptors—eagles, hawks, and owls. Bill Robinson, director of the Raptor Rehabilitation and Research Center, will show slides and a short film and discuss the life histories, habitats, and adaptations of these birds. Several live birds will also make an appearance. *Birds of Prey* is free for members, $3 for nonmembers, and will take place on Sunday, April 12, at 1:00 P.M. (for children under age 7) and again at 3:00 P.M. (for all ages).

Growing Better

Forever Young, a new documentary film by Robin Lehman, will be shown in the Auditorium on Sunday, May 3, at 2:00 P.M. The film looks at successful aging in America, focusing on people over 65, who talk about what growing old means to them. This Education Department program is free.

Southeast Asia Month

The performing arts of Southeast Asia are the special programs in the People Center this month. Featured every weekend from 1:00 to 4:30 P.M. will be the dance, folklore, and music of Indonesia, Thailand, and Malaysia. A few examples of the many programs offered are *Balinese Dance*, *Folklore and Dance of West Java*, and *Music of Indonesia*. The free People Center weekends are sponsored by the Education Department.

For more information about any programs listed in this section, write to the appropriate department at the American Museum of Natural History, Central Park West at 79th Street, New York, N.Y. 10024, or call

RATES AND STYLE INFORMATION

$1.75 per word; 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired. Occasionally, slight editing is required for clarity. Thank you!

Celestial Events

by Thomas D. Nicholson

The Moon Except possibly for a brief glimpse of the slim, late crescent during dawn on the first of the month, don't expect to see the moon until a few nights after the April 4 new moon. The earliest view of the thin, waning crescent should come on the evening of the 7th, with the moon in Taurus, between the bright, reddish star Aldebaran and the closely packed group of stars known as the Seven Sisters (or the Pleiades). First-quarter moon on April 11 will be near Castor and Pollux (in Gemini) and full moon on April 19 will be near Spica (in Virgo). Thereafter, the moon is in the morning sky. Last-quarter moon is on April 27, new moon in May on the 5th, and first-quarter on the 10th.

Stars and Planets Evening planets have been scarce so far this year (for half of February and most of March there was only Mars, which barely made it), but this month they come back in a stampede. Three planets make the transition into the evening sky in April (Mercury, Venus, and Pluto) and one more in May (Uranus). So, even though Mars is going the other way (into the morning sky), six of the planets will be evening stars (above the horizon at sunset) at some time during April.

Despite all the shifting around in the morning and evening sky, however, only two planets, Jupiter and Saturn, are easily visible in April and early May. In the morning they are in the west, setting during morning twilight. To find them, just look for the brightest starlike object in the sky. That will be Jupiter. The "star" near it is Saturn. The next nearest bright star (about as bright as Saturn) is Spica. Jupiter and Saturn remain close to each other throughout April and May, although the brighter Jupiter separates slowly to the right (west) of Saturn. Both planets are moving retrograde (westward) relative to the stars around them, Jupiter more rapidly than Saturn. You can readily observe their movement by comparing their positions, night by night, with Spica, to their left (east).

The sun is in the constellation Pisces until late in April and then moves into Aries. Mercury spends time in Aquarius in early April, in Pisces after midmonth, and in Aries before the end of April. Venus and Mars are in Pisces at the beginning of April and move into Aries after midmonth. Jupiter and Saturn are in Virgo, Uranus is in Libra, Neptune in Ophiuchus, and Pluto is along the border between Virgo and Bootes.

April 2: Mars is in conjunction with the sun, leaving the evening sky as it shifts to the sun's morning (right) side.

April 5: Perigee moon (nearest the earth) occurs today, about twenty-four hours after new moon. The effect of perigee will enhance the normally strong spring tides that accompany the new moon.

April 7: Venus is in superior conjunction (in line with and beyond the sun), passing the sun from right to left. This takes it into the evening sky, where it will be seen in the late twilight toward the end of June.

April 16–17: Tonight will bring an exceptional opportunity to watch the moon slide past Jupiter and Venus. After sundown, the three objects are above the eastern horizon, the gibbous

moon so bright that only the two bright planets can be seen near it. Jupiter (the brighter) will be to the moon's right, Saturn below. In a short time, the moon's motion will be apparent, and the arrangement changes through the night as the objects move across the sky. The moon passes closest to Jupiter at about 8:00 P.M., EST, closest to Saturn about 1:00 A.M., EST (on the 17th). The bright star east of them is Spica.

April 17–18: The moon (one day closer to full) is near Spica, with Jupiter and Saturn to their west (right).

April 20: The moon is at apogee (farthest from the earth).

April 21–22: The Lyrid meteor shower, reliable but not particularly productive (about 15 meteors per hour), is at maximum. Look for meteors after 1:00 A.M.

April 27: Mercury, at superior conjunction, moves to the sun's left and becomes an evening star.

May 3–4: The perigee moon, coming within an hour of new moon, will enhance spring tides tonight and tomorrow. The effect of perigee will be much stronger than in early April, since it comes so close to new moon. The Eta Aquarid meteor shower (about 20 per hour, but often bright) is at maximum on the morning of the 4th.

May 10–11: The first-quarter moon tonight is near Regulus, the brightest star in Leo, moving closer to it during the night. The moon passes above Regulus during the day on the 11th, and will be seen moving away from the star during that evening.

May 13–14: The gibbous moon is near Jupiter early tonight, passing above it at about 10:00 P.M., EST, then passing above Saturn.

The Amazing Stirling Cycle **Hot Air Engine**

Heat is the only fuel required!

7¼" x 4"

Silent
Safe
Fully Tested

ALL METAL
SPEEDS TO 1000 RPM
BUILT-IN ALCOHOL BURNER

A marvelous opportunity to acquire an early model Stirling Cycle Engine and acquaint yourself with little known facts about a product of the past that may well hold promise for the future.

The average person has never heard of the Stirling engine, so the sight of one quietly running with heat as its only fuel will at first amaze them and then excite their imagination. This is the first in a family of six different desk-top model hot air engines to be issued during the next three years.

Experimenters • Hobbyists' Power Source
Students • Collectors • Model Engineers

An easily read, lavishly illustrated, 128-page book accompanies each engine or may be purchased separately. This publication, the first of its kind, takes the reader on a 160-year tour through the world of Stirling Cycle Engines. Illustrations include the Stirling, Roper, Heinrici and the amazing new Stirling-powered Ford Torino!

Elephants (p. 30)

A good general source on the natural history, ecology, and behavior of elephants is I. and O. Douglas-Hamilton's popular account of their field research in Tanzania, *Among the Elephants* (New York: Viking Press, 1975). A recent article by O. Douglas-Hamilton, "Africa's Elephants: Can They Survive?" (*National Geographic*, November 1980, pp. 568-603) focuses on how ivory poachers, destruction of elephant habitat, and political upheaval throughout Africa are threatening the elephant's survival, and includes a census of Africa's elephant population by I. Douglas-Hamilton. Publications dealing specifically with the Tana region, however, are rare. In "Water Availability and Its Influence on the Structure and Dynamics of a Savannah Large Mammal Community" (*East African Wildlife Journal*, December 1975, pp. 265-86), D. Western describes an environment similar to that of the Tana, the Amboseli region of Kenya, where highly seasonal water availability has an important effect on the structure and efficiency of the large mammal community. *Rangeland Management and Ecology in East Africa*, edited by D.J. Pratt and M.D. Gwynne (London: Hodder and Stoughton, 1977), describes the ecology of grasslands and bushlands such as those in the interior of the Tana region. S. Holman gives an account of a campaign waged against traditional elephant hunters in the Tsavo Park region, adjacent to the Tana, in *Massacre of the Elephants* (New York: Holt, Rinehart and Winston, 1967). G. Caughley gives a critique of different hypotheses on elephant management in Africa in "The Elephant Problem—An Alternative Hypothesis" (*East African Wildlife Journal*, December 1976, pp. 265-83).

Street Urchins (p. 40)

Originally published in 1890, J.A. Riis's forceful indictment of New York City's slum tenements, *How the Other Half Lives* (New York: Hill and Wang, 1957), contains a section on "street Arabs." Riis's highly personal and reminiscent narrative is, unfortunately, occasionally marred by a paternalistic, ethnocentric tone. Meant as a workbook for children in religious secondary schools, B. Peachment's *The Defiant Ones* (Oxford: The Religious Education Press Ltd., 1969) presents, through drama, the biography of Father Borelli and other twentieth-century social workers. Australian novelist M. West's *Children of the Sun* (London: Heinemann, 1957) is a sympathetic, illustrated dramatization of the plight of Naples' street urchins—the *scugnizzi*—and the story of Father Borelli's efforts to aid them. *A Street Lamp and the Stars* (New York: Coward McCann, 1963) by M. Borelli and A. Thorne, is Father Borelli's autobiography. The screenplay of Luis Buñuel's *Los Olvidados* is translated by N. Fry in *The Exterminating Angel, Nazarin, and Los Olividados* (New York: Simon and Schuster, 1972).

Tana River elephant James Allaway

Meteorites (p. 52)

Among the most useful books on meteorites are such standards as B. Mason's *Meteorites* (New York: John Wiley and Sons, 1962); E.L. Krinov's *Principles of Meteoritics* (New York: Pergamon Press, 1960); F. Heide's *Meteorites* (Chicago: University of Chicago Press, 1957); and J.A. Wood's *Meteorites and the Origin of Planets* (New York: McGraw-Hill Book Co., 1968). A comprehensive introduction to space science, *Space Geology*, by E.A. King (New York: John Wiley and Sons, 1976), includes chapters on meteors, tektites, craters, terrestrial impact craters, and asteroids, and also contains a glossary. G.J. McCall's basic exposition *Meteorites and Their Origins* (New York: John Wiley and Sons, 1973) offers a large, useful bibliography. Designed as a reference work on solar system studies, *The Moon, Meteorites, and Comets*, vol. IV of *The Solar System*, edited by B.M. Middlehurst and G.P. Kuiper (Chicago: University of Chicago Press, 1963), provides a section on meteor-

ites, their chemical composition and ages, meteoritic impacts on Earth, and the crater-forming process. *Out of the Sky* (New York: Dover Publications, 1959) and *Our Stone-pelted Planet* (Boston: Houghton Mifflin, 1933) are nontechnical introductions to meteoritics by H.H. Nininger. *Yamato Meteorites Collected in Antarctica in 1969*, edited by T. Nagata (Tokyo: National Institute of Polar Research, 1975) is a technical report of the general properties of the meteorites found in Antarctica's Yamato Mountains. "Antarctica: A Deep-Freeze Storehouse for Meteorites," by W.A. Cassidy, E. Olsen, and K. Yanai (*Science*, November 18, 1977, pp. 727–31), explores how the arctic environment preserves meteorites for long periods of time under very clean conditions. W.K. Hartmann's "Cratering the Solar System" (*Scientific American*, January 1977, pp. 84–99) analyzes craters on different celestial bodies, including Earth, and stresses the importance of cratering as a key to the solar system's history. In "Apollo Objects" (*Scientific American*, March 1979, pp. 54–65), G.W. Wetherill discusses this class of asteroidlike bodies, whose orbits cross the earth's orbit and which may be comet nuclei that have lost their volatile components. An article by Wetherill, "The Allende Meteorite," appeared in *Natural History*, November 1978, pp. 102–107. L. Grossman's "The Most Primitive Objects in the Solar System" (*Scientific American*, February 1978, pp. 30–38) is an essay on carbonaceous chondrites, mixtures of minerals that condensed out of the solar nebula. In "Did a Supernova Trigger the Formation of the Solar System?" (*Scientific American*, April 1978, pp. 124–39), D.N. Schramm and R.N. Clayton propose that measured isotope ratios can be combined with other evidence to construct a tentative account of events that gave rise to the solar system.

Lucy in the Sand with Footnotes

by Matt Cartmill

LUCY: THE BEGINNINGS OF HUMANKIND, by Donald C. Johanson and Maitland A. Edey. *Simon and Schuster, $16.95; 409 pp., illus.*

She lived unknown, and few could
know
When Lucy ceased to be;
But she is in her grave, and oh,
The difference to me!
William Wordsworth

When Don Johanson christened his 3.5-million-year-old Ethiopian woman-ape, what he had in mind was John Lennon's *Lucy in the Sky with Diamonds*, not Wordsworth's sweetheart. But the Wordsworth version fits better: dead woman, dates uncertain, nameless grave. And oh, the difference to Johanson—and to anthropology in general. Since that November afternoon in 1974 when he and Tom Gray hugged each other and danced a jig among Lucy's half-buried remains in a gully near the Awash River, Johanson has been transformed from a brash young Ph.D. with a nervous grin and a promising Pliocene site into a paleoanthropological superstar with a trunkful of the most dazzling fossil-hominid jewels ever to come out of the East African hominid mines.

The late Louis Leakey spent half a lifetime prowling and sweating up and down Tanzanian arroyos to amass a similar collection of fossils. It took Johanson and his team just two field seasons to come up with Lucy—a hominid skeleton that is more than *3 million years older* than the next-oldest reasonably complete skeleton of a human ancestor. The following year, Johanson's group found the remains of thirteen or more individuals in a clump, all apparently killed at once by a flash flood—a sort of quick-frozen primeval horde that gives us the only evidence we have about the variability and composition of early hominid bands. The year after that, the group found the earliest-known stone tools. Any one of these finds would be enough to catapult the finder into international prominence and turn competitors green with envy. Johanson's competitors and colleagues, myself included, have been Day-Glo chartreuse for the past five years.

In the late 1960s, when Johanson was a graduate student, there were three broad schools of thought about human evolution. Each school had a different idea about the number of hominid species that had coexisted in the African Pleistocene, and so they were sometimes called the one-, two-, and three-species schools. Their real disagreements, however, were about what it means to be human. The two-species interpretation, which Johanson absorbed from his teachers at the University of Chicago, had its roots in the thinking of Raymond Dart and his view of man as Killer Ape. According to this school, early hominids were of two sorts, corresponding roughly to Lennie and George in John Steinbeck's *Of Mice and Men*. There was *Paranthropus*, a big, dumb vegetarian type, and *Australopithecus*, a small, wiry meat eater who subsisted by bashing the local fauna with slightly sharpened rocks. As time went on, according to the two-species scenario, the nasty little killer got smarter and handier with rocks, exterminated the big herbivore, and went on to evolve into Man the Hunter.

The one-species believers were egalitarians with vaguely leftish antecedents (notably Leslie White and G. F. Gause), who traced hominid origins to tool using and believed that it was impossible for more than one such tool-using, culture-bearing species to exist at a single time. In their view, *Paranthropus* was neither retarded nor herbivorous, but just an intermediate population on the lineage leading from *Australopithecus* to *Homo*—and all three probably ought to be called *Homo*. Some fans of Marx who clung to the fringes of this school weren't above hinting that the two-species people were closet apologists for apartheid. Finally, the three-species school saw the brain as the hallmark of humankind and held that most known fossils, with their jutting brows and receding foreheads, could not possibly be ancestral to university professors.

The three-species school got its nickname from the ideas of its leading exponent in the 1960s, Louis Leakey, who devoted his career to searching for advanced *Homo* in the early Pleistocene of Africa. At Olduvai Gorge, he believed he had found, in addition to a *Paranthropus* and a beetle-browed *Homo erectus*, a gracile hominid with a small brow ridge and a respectably large brain. Leakey and his coworkers christened this third species *Homo habilis*, and Leakey acclaimed it as the true ancestor of *Homo sapiens*. Almost every anthropologist pooh-poohed this notion. The two-species people insisted that early *habilis* was just *Australopithecus* and later *habilis* was just *H. erectus*. The single-species enthusiasts, perplexed at first by finding supposed ancestors and descendants living side by side, finally decided that the little *Paran-*

thropus types were females and the big ones were males.

This last-ditch effort to save the single-species theory foundered in the early 1970s when Louis Leakey's son Richard began uncovering dozens of beautiful early hominid fossils from the Koobi Fora area in Kenya. These finds included great flat-headed *Paranthropus* forms like the ones from Olduvai, all chewing muscles and no forehead, as well as unmistakable *Homo* with a delicate brow ridge and a relatively roomy, high-vaulted braincase. Richard Leakey's prize *Homo* specimen, number 1470, was an astonishingly modern-looking skull dated by the potassium-argon method to almost three million years ago—about a million years older than the oldest fossils at Olduvai. The single-species theory kicked feebly and expired. With 1470 in the picture, all the competing theories seemed too simple-minded. It began to look as if the hominid family tree had resembled a dense bush, with many little local species pursuing their own specialized evolutionary careers. A theoretical vacuum appeared at the heart of human evolutionary studies and grew throughout the 1970s.

At first, Johanson's finds in the Awash River valley spawned even more confusion. His site of Hadar seemed to be about the same age as Koobi Fora; the earliest datable deposits at Koobi Fora were some 2.6 million years old, those at Hadar only about 400,000 years older. The two sites were no more than 500 miles apart. But Hadar's hominids looked nothing like Koobi Fora's. They included little things like Lucy—a dwarfish, half-simian biped about

three and a half feet tall, with a V-shaped lower jaw and a head the size of a softball—as well as larger creatures fully human in stature but with their molar teeth set in parallel rows like a chimpanzee's. Where was 1470 in this picture? Had he popped into existence in a mere 400,000 years by some sort of macromutation? Where did *Homo* come from, and why?

In the last three years, this series of puzzles has been partly solved, and a new picture of human evolution is beginning to emerge. The crucial step was realizing that 1470 was a million years younger than Richard Leakey had thought. The Koobi Fora site had a suspicious aroma from the beginning; not only was the 1470 skull a million years more advanced looking than other 3-million-year-old hominids, but it was surrounded by equally precocious horses, pigs, and elephants. The current consensus, based on new potassium-argon dates, is that the Koobi Fora deposits are only slightly older than the lowest levels at Olduvai and that there is no good evidence for *Homo* prior to about 2 million years ago. But there are now lots of hominid fossils from almost 4 million years ago: from the Hadar site (which the latest estimates date back to something over 3.7 million years), and from Mary Leakey's site of Laetoli. The great contribution of Johanson and his colleagues has been to sort out these earlier hominids and provide a sensible scheme for hooking them up with the later ones.

In 1976, Tim White, who had worked at Koobi Fora and had described the Laetoli hominids, began trying to convince Johanson that the Hadar and Laetoli hominids represented a single species. Two years of argument, calculation, and browbeating punctuated with sarcasm brought Johanson around, and in 1978 he and White assigned all the Hadar and Lae-

Lucy (Australopithecus afarensis) Cleveland Museum of Natural History

toli hominids to a new species: *Australopithecus afarensis*. Johanson and White regard this species as ancestral both to the later *Australopithecus* lineage (terminating with *Paranthropus*) and to the *Homo* lineage (from *habilis* to *erectus* to *sapiens*). This hypothesis makes concessions to all the old theories from the sixties. The one-species school was right in claiming that *Australopithecus* evolved into *Paranthropus*. They were also right in thinking that sexual dimorphism—the sum of differences between males and females—was greater in early hominids than it is in ourselves; Johanson and White now see the larger Hadar hominids with their U-shaped jaws and big front teeth as hulking male counterparts of the smaller females, such as Lucy. The three-species people were right in believing in an early separation of *Homo* and *Australopithecus* and in insisting that *habilis* was a separate species. The two-species people were the most nearly right of all; they erred only in trying to squeeze the later *Australopithecus* into the human ancestry.

The theoretical vacuum—the question of how we got where we are and what it means, which is what lends significance to all this gnawing of dead bones—remains to be filled. Big brains are out as a causal factor in early hominid evolution. Even tool making is starting to look less important, at least so far as *Australopithecus* is concerned. We know from the Hadar fossils (and from the astonishing discovery of a trail of hominid footprints in a volcanic ashfall at Laetoli) that these earliest undoubted hominids were, despite their ape-sized brains, upright bipeds like ourselves. They had short-fingered, human-looking hands that were suited well enough to making and using tools. But there is no evidence that they did so. Stone tools don't appear in the fossil record until just over two million years ago. Wherever stone tools are found, so is early *Homo* (with the minor exception of one late *Paranthropus* site from South Africa). If we accept the evolutionary tree offered by Johanson and White, the evidence suggests that the use of stone tools was a later invention that appeared in the *Homo* lineage at about the time the brain began to expand—which is probably not a coincidence. But the *Australopithecus* line of small-brained bipeds continued to survive alongside early *Homo* and his stone tools. *Australo-*

pithecus just went on getting bigger, more herbivorous, and (judging from its relative abundance at Koobi Fora) more successful, until it perished of unknown causes about one million years ago. Bipedality persisted in the *Australopithecus* lineage for more than two million years without any association with big brains or stone tools. So what is bipedality good for, if not freeing the killer ape's hands for holding weapons? Johanson's tentative answer, taken from his friend and collaborator Owen Lovejoy: sex. Making babies.

Lovejoy's reasoning, which Johanson and Edey set forth in forty pages of quasi-Platonic dialogue, runs roughly as follows. Twelve million years ago, apes were common and monkeys were rare. Today, things are the other way around. What happened, in Lovejoy's view, is that the apes found themselves trapped in a pattern of natural selection that favored a progressive increase in brain size, requiring ever longer infancies and greater intervals between one birth and the next. In the time it takes a female chimpanzee to reach puberty and have her first baby, a female baboon has already raised four. Faced with this sort of competition, the apes are doomed. The hominids represent the only group of apes that has come up with a solution to this problem, namely, the two-parent family unit, in which Mom sits home lactating and gestating while Dad goes out to bring home the carrion. Bipedalism frees the hands, not so much for tool use as for hauling around helpless offspring and for carrying food. Hence our upright posture, our closely spaced births, capacity for romantic love, unflagging interest in year-round sex, and lemminglike overpopulation of the world. This view of a male-provisioned nuclear family as the cornerstone of human existence is sure to provoke a hot controversy, in which I am reluctant to participate beyond pointing out that birth spacing in South African hunting peoples and Tanzanian chimpanzees is about the same.

Johanson and Edey have written an uncommon sort of book to explain Johanson's finds and what they mean. Edey, an assistant editor at Time-Life Books, seems to have done most of the writing. Despite this, the book is written in an "I, Don Johanson" format, like an as-told-to biography of a film star. This artifice made me grate my teeth for about the first ten pages; then I got interested and forgot about it. The book is partly a professional memoir, partly a compressed history of paleoanthropology, and partly a popular treatment of current knowledge and guesses about human evolution. These three strands of the book loop in and out of each other in a fluid and ingratiating way that is obviously the work of a professional writer who knows his stuff. The scientific exposition is fascinating, thorough-going, and easy to follow; even complete novices will find themselves picking up a surprisingly detailed understanding of everything from potassium-argon dating to the importance of the ectostylid in identifying fossil horse teeth. The authors have seized on the increasingly popular gimmick of using dialogue to put across technical points in colloquial language. This works well as long as the reader doesn't start wondering how on earth Johanson got a verbatim transcript of a chat Clark Howell had with Louis Leakey in 1965. The passages recalling the history of paleoanthropology are a delight to read. Even jaded professionals will enjoy Basil Cooke's explanation of what "MCP" stands for, or Robert Broom's remark that a col-

league's brain "was remarkably good for its size."

Fossil hominids have always been the number-one glamour stock on the paleontological bourse, bringing their discoverers fame and fortune of a sort forever denied to those who study extinct clams. It is no wonder that people who work on fossil hominids are notorious for the intensity and bitchiness of their rivalries. Johanson and Edey's book shows us some of these rivalries from Johanson's point of view, and the descriptions of his antagonists are not flattering. Richard Leakey, for example, is introduced as an "obscure bushwhacker" who spurned a university education to become a white hunter and safari guide, stumbled across Koobi Fora in a snit while evading distasteful work at another dig, and barred Tim White from Koobi Fora when he dared to voice a dissenting opinion about the date of the 1470 skull. Happily, Johanson can take it as well as dish it out. Even Richard Leakey would probably relish the quotes from White describing Johanson as "a nail-polish salesman . . . who wears Gucci loafers and Yves Saint Laurent pants." Nevertheless, Richard and Mary Leakey, Solly Zuckerman, Jon Kalb, and four or five other anthropologists are going to get no pleasure out of reading this book.

The rest of us will. In the present dark days, when impassioned ignoramuses across the country are marshaling their forces to get Noah's ark put into the Constitution, a book like this is of enormous value. Entertaining and informative without being condescending, it will give any fair-minded reader an enlightened understanding of the vast mass of minutely detailed evidence that underlies our knowledge of human evolution, and of the hard physical and intellectual work that has gone into piling up that evidence. Evolutionary biologists, whose currently intense arguments over theoretical fundamentals have hamstrung them in fending off the onrush of the Bible-thumpers, should welcome a book like *Lucy*. It puts across the excitement and headaches of studying human evolution and does the job with conviction, accuracy, and pizzazz. This book needs to be on our new President's bookshelf.

Matt Cartmill is professor of anthropology and anatomy at Duke University.

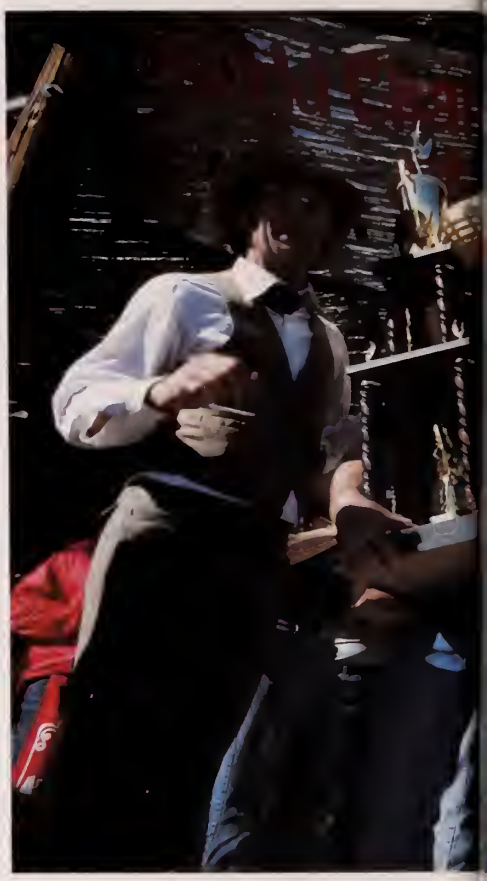
Chili con Blarney

The annual Texas chili cookoff is a bizarre and boozy food event



by Raymond Sokolov

Looking like a giant egg with eyebrows, a stranger came up to me in the lobby of an Austin, Texas, motel in 1971, proferring a plain, brown carton. I looked puzzled. He showed me his driver's license, which was Vietnamese, but gave his name as Wick Fowler. The carton contained several packets of premixed spices boldly labeled "Three-Alarm Chili." Fowler had created the jocular product to capitalize on his fame as the chief cook of the Chili Appreciation Society International (CASI), an outfit that sponsors the Annual World Championship Chili Cookoff in a Texas mining ghost town called Terlingua.

Fowler was not profaning the pristine sanctity of the Terlingua cookoff. His chili mix was by no means contemptible. And self-advertisement lies at the heart of the cookoff itself, which began as a publicity stunt in 1967. A Dallas restaurateur and journalist, Frank X. Tolbert, had concocted the contest to promote the sale of his book, *A Bowl of Red: The Natural History of Chili with Recipes*. Originally, Tolbert had planned to pit Fowler against Dave Chasen, the Beverly Hills restaurateur, whose chief stirrer was to have been Elizabeth Taylor. But Chasen fell ill, and the humorist H. Allen Smith of Mount Kisco, New York, author of a boastful mock attack on Texas chili cooks, stood in for him.

photographs by Adelaide de Menil

The result was called a draw, but the cookoff itself was a decisive success, spawning what Tolbert has called "an international subculture" involving thousands of "chili heads" who compete in CASI-sponsored local tourneys from Manila to Connecticut. Winners trek to Terlingua on the first Saturday in November for "the big showdown," which is probably the biggest, grossest, booziest, most self-inflated, and certainly most entertaining of all the thousands of American regional food events that each year purport to commemorate and preserve the hallowed and embattled dishes of yesteryear.

Second to none in my hunger for authentic American food, I traveled to Terlingua for the 14th Annual Wick Fowler Memorial World Championship Chili Cookoff. Getting to the remote patch of desert on the banks of the Rio Grande where the contest is held isn't easy. Essentially, you drive through the 8,000-foot, lunar Chisos Mountains in the Big Bend National Park, and turn right. Road runners skitter and bob across the highway. The sky is big, and the nearest town of consequence, Alpine, is eighty miles away. For cookoff weekend, Alpine's motels are full, all their rooms having

been reserved several weeks in advance. There aren't really many other places to stay in the rest of Brewster County, the state's largest, which at 5,935 square miles is bigger than Connecticut and very empty.

A century ago, when its mines provided 40 percent of the country's cinnabar, or mercury ore, Terlingua itself had 2,000 or so inhabitants. But foreign competition closed the mines, and only four permanent inhabitants remained when CASI staged the first cookoff. By now, however, the word has spread worldwide. On cookoff weekend, Terlingua hosts hundreds of chili heads and camp followers who arrive with tents and vans for the rowdiest weekend this side of Fort Lauderdale.

The contest site looked like a Hollywood mock-up of a Western town. But the real-life action was a bit more "adult" than the movie industry tends to allow. Dancers in Old West costumes gyrated at the Ball Buster Bar. They were the show business aspect of the Ball Buster Chili team. The cookoff gives an award for the best variety act of the day, which explained the frontier revival church in full swing at one end of the patio. Brother Willie and Sister Lilly's Salvation Chili team led the pagan hordes in a hymn sung to the tune of "Amazing Grace": "Salvation chili came to me/ And saved my soul from grief./ It cured my pimples, healed my toe/ And put me on relief. . . ."

The crowd was dressed in a variety of costumes, ranging from obscene T shirts to the height of urban cowboy dandyism—an all-rattlesnake-skin vest decorated with several huge rattles and fossilized shark's-teeth all set about with turquoise and silver. The crowd, restless with anticipation and primed with Texas beer, gathered to watch young women vie in a wet T-shirt contest and young men take their pants off for the "equal opportunity" hairy legs competition. At the height of the frenzy, a voice on the public address system announced: "Matt Butler lost his pistol. Nickel-plated. Whoever finds it, there's a reward. If that's necessary."

Meanwhile, at the edge of the festivities, a motley collection of men and women were devoting themselves with solemnity to the preparation of chili. For them it was a serious day of judgment.

Connecticut champ Jim Hibbits, wearing a frock coat and top hat, stirred and tasted his Ugly Butcher Chili. Wayland Walker of Ardmore, Oklahoma, told passers-by how he had turned to chili out of desperation, when a slaughterhouse miscut a whole beef he had purchased from the local sheriff. Some sixty contestants labored over their pet chilis all through the forenoon, hoping that greatness would be thrust upon them by the CASI judges. Most of the cooks used whole chili peppers, not prepared powder. And they followed CASI rules, which insist on beef and forbid all vegetables except onions. This not only eliminates exotic ingredients such as pineapple but also excludes beans. At Terlingua, beans are viewed with alarm, as a contaminant of what Texas governor Bill Clements hailed in an official proclamation as "unadulterated Texas chili."

My own random tasting of the chilis-in-progress reminded me how much variation there can be on an apparently simple culinary idea. Even with the CASI restrictions, no two chilis tasted alike. Recondite spice combinations and varying dosages produced a wide spectrum of flavors, as well as levels of hotness ranging from mild to infernal.

Judges assembled at lunchtime on a protected upper level and began their tongue-singeing task, clearing their palates with beer between tastes, doing their best to rate each entry on a ten-point scale based on five criteria: aroma, red color, consistency, taste, and aftertaste.

No one disputed their final decision to award the world championship to Brother Willie and Sister Lilly's Salvation Chili. But any objective bystander who had not entirely succumbed to the soporific powers of Texas sun and brew was left wondering what it all meant. Was Terlingua merely a ribald exercise in boosterism and self-parody or did the cookoff really help to maintain the purity of one of the nation's best known and most polymorphous regional dishes?

At issue is the whole vexing notion of authenticity in food. CASI's rules are a laudable attempt to codify and preserve what one of its members asserted to me was an invention of the frontier, a simple beef stew seasoned with regionally abundant capsicum (chili) peppers and other spices (usually cumin, oregano, and garlic) and onions (see recipes). Also, the Ter-

lingua chili heads are certainly right to abominate *outré* variations such as Cincinnati three-way chili or the bland bowls of ground meat and beans served at every nondescript lunch counter in the land.

On the other hand, all the Lone Star chauvinism at Terlingua overlooks certain obvious factors that must have contributed to the evolution of chili con carne. The dish obviously did not originate entirely among English-speaking Texas ranchers. The influence of Mexico, within sight across the river from Terlingua, shows itself in the part-Spanish, part-Nahuatl name. "Chili" is a descendant of the Aztec term for capsicum peppers. And it simply must be the case that modern chili arose through the contact of nineteenth-century white immigrants with native Indians and Mexicans. This of course is where all of the so-called Tex-Mex foods began. Chili is merely the most popular among them, mixing the Mexican tradition of sauces flavored with chili (and other spices typical of Mexican food) with the European notion of a beef stew based on chunks of browned meat.

All through the American Southwest different variations on the same theme have sprung up and prospered. Consider chili with beans, green chili made from green chili peppers, or chili with ground meat. You will find chili served at Indian pueblos and at the Tigua Indian Reservation in El Paso. There is even quite "authentic" chili in Arizona and other non-Texas locations in the Southwest.

To be fair, the Terlingua cookoff is not purely isolationist. It promotes the worldwide proliferation of its kind of chili. But the motive behind CASI is still intrinsically self-contradictory. CASI wants to protect traditional Texas chili, as if it were a dish handed down over generations by a coherent culture, fixed as to its ingredients and style of preparation in one basic ancestral recipe. But the very essence of chili con carne is its cultural diversity and lack of culinary fixity. At Terlingua, the chili heads, while claiming to preserve a traditional recipe, are in fact trying to create one. So remember, the next time you start to put beans in your chili, the eyes of Texas are upon you.

Raymond Sokolov, a writer with an interest in the history and preparation of food, is editor of Book Digest.

Frank X. Tolbert's "Simplified Texas Chili"
(Adapted from a text in *Flying Colors* Magazine)

- 3 pounds lean beef
- 2 ounces suet (or substitute vegetable oil)
- 2–4 chilis anchos
- 2 tablespoons cumin
- 1 tablespoon oregano
- ½ cup paprika
- 1 tablespoon cayenne (optional)
- 1 sprig fresh coriander (cilantro), chopped
- ⅓ cup finely chopped garlic

1. Cut the beef into bite-sized chunks.
2. Render the suet in a heavy skillet, and sauté the beef chunks until they turn gray.
3. Pour the liquid from the skillet into a heavy pot, leaving a small amount in the pan. Continue cooking the meat until it is well browned on all sides.
4. Meanwhile, remove stems from chilis and purée in a blender with a small amount of water. Add purée to chili pot.
5. When meat is browned, add it to the chili pot and simmer for 30 minutes.
6. Add remaining ingredients and simmer for another 30 minutes or until meat is tender. (Use choice chuck. That old myth about bull meat is not for the Tolberts.)
7. Keep the chili overnight; in the morning, scrape off the grease that comes to the top.

Yield: 6–8 servings

Lone Star Texas Chili with Beans

- 2 tablespoons vegetable oil
- 2 pounds stewing beef, cubed
- 1 cup chopped onions
- 1 green bell pepper, seeded and chopped
- 1 clove garlic, minced
- 1 12-ounce can tomato paste
- 2½ cups water
- 2 pickled jalapeño peppers, rinsed, seeded, and chopped
- 1½ tablespoons chili powder
- ½ teaspoon crushed red pepper
- ½ teaspoon salt
- ½ teaspoon dried oregano
- ½ teaspoon cumin
- 1 15½-ounce can pinto beans, drained

1. In a large, heavy pan, heat oil and brown beef cubes on all sides. Add onions, bell pepper, and garlic and fry with beef for about 5 minutes.
2. Add all the remaining ingredients except beans, and simmer the chili for 1½ hours or until the meat is tender.
3. Add beans and simmer 30 minutes longer.

Yield: 4–6 servings

Things of quality have no fear of time.

Time is the enemy of all things made. It weakens. It lessens. It wears out the most carefully-built products.

But as a maker of home appliances, Whirlpool Corporation believes there are ways of taking the sting out of time. Taming it to a point where it's always respected, but never feared.

We know the real challenge comes after the sale. When new becomes used. And used becomes old. This is why we take pride in stocking parts for as many years as we do. And why we maintain a toll-free Cool-Line® service number* you can call 24 hours a day. And why we have a nationwide organization of authorized Tech-Care® service companies that are as close to you as your phone book.

You see, at Whirlpool we believe quality is not something to be flicked on and off like a neon sign. We believe it should be a philosophy of excellence dedicated to one person—you.

It's our way of saying this is more than just an appliance. This is our way of life.

Now...an exact 22kt gold replica will be created for each new U.S. Commemorative Postage Stamp!

22kt Gold Replicas of United States Stamps

Exact replicas on a gleaming surface of real gold.

Under a non-exclusive licensing agreement with the U.S. Postal Service, the Postal Commemorative Society is proud to make available an authentic replica of each new U.S. Commemorative Stamp—recreated to exacting standards with high-relief sculptured detail on a flawless, mirror-smooth gold surface. Accompanying each mint-perfect replica is the actual stamp, cancelled with the Official First Day of Issue Postmark. The result is a collectible of unsurpassed meaning, beauty, and importance. And, if you reply promptly, you have the opportunity to start your collection at the favorable price of just $5.50 each.

Nothing captures the grandeur and glory of this land like America's stamps. For here is where we honor the men and women who made this nation great. Where we relive the high points in our history. Where we rejoice in America's magnificent natural beauty. Where we pay tribute to our customs and folklore, institutions and ideals. Each new stamp is a patriotic treasure. And each is also an important original work of art—created by one of America's finest living artists.

Imagine the excitement, then, when each new stamp is immortalized on a gleaming surface of 22kt gold!

Each 22kt gold stamp replica will be authentic down to the smallest detail.

For each new commemorative stamp that is issued, the U.S. Postal Service makes available a photograph of the original design. From this photograph, the stamp is then recreated on sheets of paper-backed 22kt gold precisely to the original's size, shape, and official design.

First, the skilled craftsman hand-inscribes every line and stroke of the original in raised relief upon a master model from which a die is created. The die is then used to strike the 22kt gold surface in a flawless proof-like finish—just as if one were producing a magnificent medal or coin. The result is not an ingot or a medallion—but a dramatic, three-dimensional sculpture, standing in high relief on a mirror-surface of gleaming gold!

Much in the manner of a precious medal or coin, each proof-like gold replica is displayed against a rich velvety background—and preserved forever in a clear protective capsule to guard against dust, loss, or harm from fingerprints. A perfect mint specimen for your children, your grandchildren, and their children to enjoy in years to come.

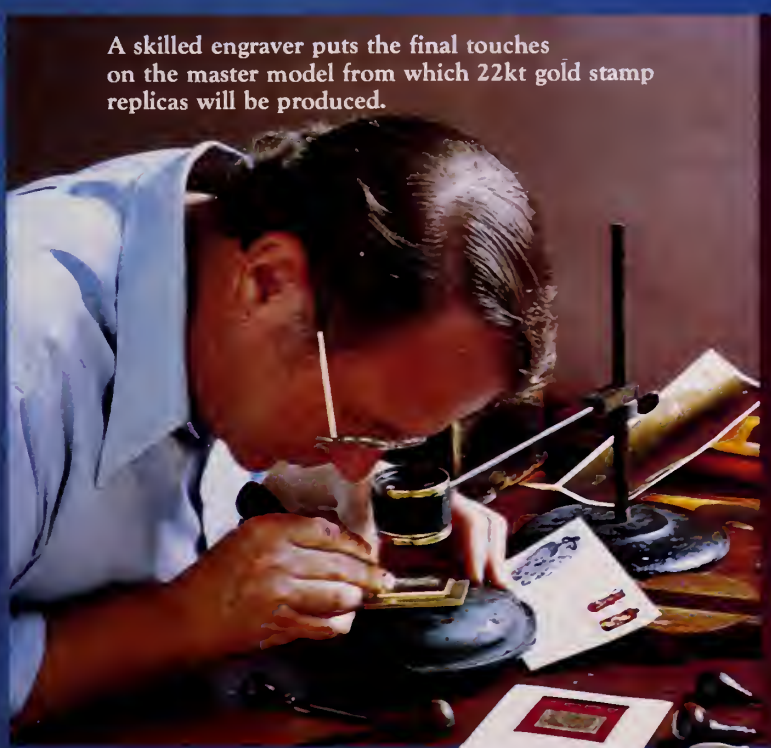
The actual First Day of Issue Stamp attests to the faithfulness of the replica!

Perfectly complementing the gold stamp replica is the actual stamp—bearing the Official First Day of Issue Postmark to certify that these gold replica-bearing First Day Covers can never again be issued. As you examine the intricate details on both the stamp and its replica, you will see how perfectly the two correspond!

A custom-crafted collector's album will showcase your collection to best advantage.

Your name will be stamped in gold on the front

22KT GOLD REPLICA. Not an ingot or a medallion but an exact replica of a U.S. Commemorative Postage Stamp, struck on a gleaming surface of 22kt gold.



OFFICIAL FIRST DAY OF ISSUE POSTMARK, certifying each cover as an Official First Day Cover, which can never again be issued.

PROTECTIVELY ENCAPSULATED to guard against dust, scratches, and fingerprints. Each gold stamp replica is permanently sealed in the cover and set against a rich velvety background.

PERSONALIZED with your name and address, if desired.

THE OFFICIAL U.S. COMMEMORATIVE POSTAGE STAMP—which is the basis for each 22kt gold replica.

A skilled engraver puts the final touches on the master model from which 22kt gold stamp replicas will be produced.

A final striking is inspected to insure that it meets the high quality standards established for 22kt Gold Replicas of United States Stamps.

(continued on next page)

Covers shown smaller than actual size.

NOTE: The stamps and replicas shown in this presentation are from past issues and are shown for illustrative purposes only. You will receive replicas of future U.S. Commemorative Stamps as they are issued.

(continued from previous page)

cover. Inside, transparent vinyl pockets will display each cover. You may slide each cover from its pocket for closer inspection and still not worry about the gold stamp replica itself—sealed within its own protective capsule.

Subscribe now for a favorable issue price.

Subscribing before the end of the current enrollment period guarantees that you will be enrolled at the favorable issue price of $5.50 per cover. This price includes the gold stamp replicas, the protectively sealed capsules, the First Day of Issue stamps, the official postmarks, the display pages, the clear vinyl pockets, and your personalized collector's album. The value is all the more remarkable when one notes that other covers bearing gold stamp replicas have been offered to collectors for more than twice the price!

No payment needed now.

You need send no money now. Simply return the application on the right before July 31, 1981. As a subscriber, you can expect to receive your covers approximately 8 to 10 times each year, depending on the Postal Service's schedule of new commemorative releases, with 3 covers per shipment. You will be billed with each shipment.

Join us for this magnificent philatelic tribute to the greatness of America—a collection that surpasses anything previously seen. A collection that you and your family will treasure for untold generations to come!

22kt Gold Replicas of United States Stamps

Postal Commemorative Society
47 Richards Avenue
Norwalk, Conn. 06857

Guaranteed acceptance
at the price quoted herein only
if postmarked by July 31, 1981

Please enroll me as a subscriber to **22kt Gold Replicas of United States Stamps.** I will receive a gold stamp replica for each and every new U.S. Commemorative Stamp. I can expect to receive my gold stamp replicas approximately 8 to 10 times each year (depending on the U.S. Postal Service's schedule of new commemorative stamp releases), in sets of three each.

I will be billed $5.50 (plus $.50 shipping and handling) for each gold stamp replica. I will be billed as each shipment is sent to me. A custom collector's album will be sent to me at no additional charge. I understand that either party may cancel this subscription agreement at any time.

☐ As a convenience, I prefer to have my 22kt Gold Stamp Replicas charged, at the time of shipment, to my:
☐ Master (Charge) Card ☐ VISA

Credit Card Number _____ Expiration Date _____

I would like my covers:
☐unaddressed, or ☐personalized exactly as shown at right.

Mr. Mrs. Miss _____

Allow 10 to 12 weeks for shipment of initial set.

When Mount St. Helens erupted on May 18, 1980, **Roger del Moral** added the recovery of subalpine vegetation on the mountain to his research interests, which also include competition within stable alpine herb communities. "Upon hearing that a new environment had been made available for plant colonization," he says, "I could not refuse such a unique opportunity to follow how ecosystems reconstitute themselves." An associate professor of botany at the University of Washington at Seattle, del Moral has done fieldwork in Washington, California, Alaska, and eastern Australia. He enjoys landscape and vegetation photography, and when not studying the often eerie, alien landscapes of Mount St. Helens, he reads science fiction.

David B. Grobecker was hooked on anglerfish the first time he saw one in a tropical fish store. Currently a Ph.D. candidate and research associate at the College of Fisheries of the University of Washington, he is working on the morphology and feeding ecology of Antennariidae anglerfish. An interest in predatory behavior has led him to study other fishes that employ a lie-in-wait strategy, including the stonefish and carpet sharks. A fisherman himself, Grobecker is also a photography enthusiast. By means of high-speed, light cinematography, at 800 and 1,000 frames per second, and a generous measure of patience, he has been able to document the extraordinarily fast feeding mechanisms of some anglerfish.

BLENDED SCOTCH WHISKY • 86.8 PROOF • ©1980 SCHENLEY IMPORTS CO., N.Y., N.Y.

This is the land of the Vikings.

And this could only be Rio de Janeiro where the carnival pace picks up when the sun goes down.

South America.

The world's fourth largest continent. A land of mystery. Fantasy. A marvelous mélange of Indian, colonial, and contemporary European cultures. And who could show you South America better than the Royal Vikings? For we carry you to more ports, more places, more pleasures than any other cruise line on earth.

This fall we'll take you down one coast and up the other. Through the Strait of Magellan and the Panama Canal.

And though you may not find a lost Inca treasure, you may indeed return with emeralds from Colombia, pearls from Venezuela, fleecy alpaca slippers from Peru. Or a craving for the delicate langostinos (tiny crawfish) of Chile.

You'll bring home memories too. Of sophisticated cities like Lima and Valparaiso. Avant-garde Buenos Aires. Uninhibited Rio where beautiful, sun-bronzed Euro-Latins move to a different beat.

You'll sail on the Royal Viking Sky, of Norwegian registry and spirit. Our extraordinary World Class™ service means relaxed, single seating at every meal. Double cabins, nearly all outside, that look to sky and sea. And a crew that will welcome you as warmly as they would a Scandinavian summer.

Around South America sailings: Round trip from Los Angeles/San Francisco, 58 days, Oct. 15/16, calling at Acapulco and Puerto Vallarta along the golden, glittering Mexican Riviera. Plus Callao, Valparaiso, Puerto Montt, Punta Arenas, Buenos Aires, Rio de Janeiro, Salvador. Bridgetown on the Caribbean island of Barbados. Then Cartagena and Balboa.

Round trip from Florida, 63 days, Sept. 28. Or New York to Florida, 66 days, Sept. 25. These two cruises call at St. Thomas, St. John's, La Guaira, Zihuatanejo, and all ports listed above except Cartagena and Balboa.

For more information or reservations, see your travel agent. Or write Royal Viking Line, Dept. K-38, One Embarcadero Center, San Francisco, CA 94111. Then set sail for South America. It's been waiting centuries for you.

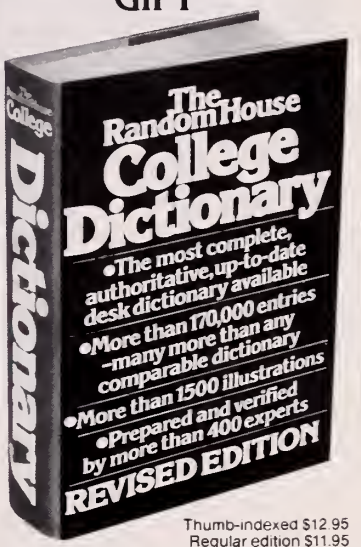
The husband-and-wife team of **Bernard Nietschmann** and **Judith Nietschmann** has ranged far afield in pursuit of anthropological and geographical studies. Mexico, Nicaragua, Peru, the Cayman Islands, the Pacific, and Australia have been the sites of their fieldwork, much of it concerned with cultures based on marine subsistence economies. Their studies of the Torres Strait Islanders' traditional knowledge of marine environments and biota were begun in 1976/77 and continued in 1980. Bernard is a professor of geography at the University of California at Berkeley; Judith is a postdoctoral fellow in the Medical Anthropology Program at the University of California at San Francisco. The author of many articles for *Natural History*, Bernard most recently contributed "The Wind Caller," which appeared in March 1977.



A doctoral candidate in the Department of Zoology at the University of Florida, **Erik J. Bitterbaum** (below, left) is completing a study on the comparative behavior of three species of swallows in the genus *Progne*. His work focuses on communication, with the objective of determining how vocal and physical displays function in the social behavior of closely related species having known differences in morphology and biology. Some light may be shed on how social behavior has evolved in these species. During his fieldwork in Mexico, Trinidad and Tobago, and Florida, Bitterbaum has become a purple martin fancier.

Coauthor **Charles R. Brown** (below, right) is a senior at Austin College in Texas, and will begin graduate work in zoology in September. He became interested in purple martins as a child when they occupied a backyard birdhouse installed by his father, and has followed the birds throughout Texas ever since. Brown, who began researching the breeding biology and behavior of purple martins in 1972, published his first technical paper on purple martins at the age of fourteen. Since then he has authored more than twenty papers on these birds. Species relationships among swallows will be the thrust of his future research.

PRESENTING OUR NEW CAMERA

When it comes to competition, the new Minolta XG-M stands alone.

How can we say that?

Simple. No other 35mm SLR in its class has its unique combination of creative features, yet is so easy to use.

All you do is point, focus and shoot. The automatic XG-M does everything else to give you clear, sharp, beautiful pictures.

It even has electronic features to prevent mistakes. And advanced features like manual metering for advanced photographers.

To separate it further from the competition, we gave the Minolta XG-M something you only find on more expensive cameras. The option of professional motor drive, to let you take pictures at an incredible 3.5 frames per second.

So you can capture fast action. Like a diver's twisting entry into the water. Or a racer's moment of triumph at the finish line.

And when you hold this camera you'll know it's extraordinary, inside and out. Its built-in textured grip was sculptured to fit your hand more comfortably. And its advanced design represents an exciting new achievement in making fine cameras. Something we've been doing for over 50 years.

The XG-M accepts over 45 interchangeable, computer-designed Minolta lenses. As well as the Minolta system of SLR accessories.

The new Minolta XG-M. It's designed to have everything.

Except competition.

WAIT 'TIL YOU SEE HOW GOOD YOU CAN BE.

AND ITS COMPETITION.

More Is Not Necessarily Better

Researchers are learning that an excess of a required nutrient may present as much of a cancer risk as a deficiency

by T. Colin Campbell

The current spate of publicity concerning the possible role of diet and nutrition in certain kinds of human cancer has led to much public misunderstanding and confusion. At various times, animal fat and an excess of protein, calories, and sugar have been implicated as possible carcinogens, whereas inadequate amounts of vitamin C, vitamin E, vitamin A, zinc, and selenium (a soil mineral that is found in most vegetables and cereal grains) have been thought to enhance the risk of cancer.

There are about forty substances required by the human body to maintain health and sustain growth. Considered individually, each of these nutrients can influence the risk of cancer in only one of three possible ways: have no effect; inhibit the development of cancer; enhance the risk. Nutrients, however, are not consumed singly but in groups in which their behavior may be altered. Therefore, if there is ever to be more clarity, we must seek to understand the effects of multiple nutrient intakes and analyze dietary patterns in terms of the ways in which the simultaneous actions of nutrients can modify the risk of cancer.

In order to better appreciate these nutrient effects, a brief description of the carcinogenic process is helpful. The simplest model divides the process into three phases: initiation; cell modification; and metastasis, or invasion of other tissues.

In the initiation phase, a normal cell is converted into a neoplastic one —that is, a cell that grows without restriction—through the process of mutation. The mutation occurs when a chemical reacts with and changes the cell's genetic material, or deoxyribonucleic acid (DNA), so that subsequent generations of daughter cells derived from the parent cell are permanently altered. A wide variety of natural chemicals, such as aflatoxin (a mold product found primarily on improperly stored peanuts and corn) and a chemical found in black pepper, as well as some synthetic chemicals are capable of acting as initiators during this phase. After ingestion, most of these initiators are metabolized by an enzyme system to reactive products that bind tightly to certain sites on the DNA molecule. If not removed or neutralized, these initiators ultimately transform normal cells into neoplastic cells, which can be either benign or malignant. When that happens, the initiation phase is completed.

Some of these initiated cells then progress over a period of years through the second, or modification, phase to the ultimate cancer cell that characterizes malignant tumor tissue. This long period is considered a latent one, in large measure because cells progressing through the series of stages involved cannot be readily detected. Some compounds may positively promote the growth of these latent cells, whereas others may inhibit that growth. The human body may, in some cases, recognize these "new" cells as foreign bodies—as it does with foreign bacteria—and destroy them by means of its immunological defense system. If this happens, the carcinogenic process is intercepted and fully developed tumor cells never appear. If, on the other hand, these latent cells escape the body defenses and receive nourishment for growth, they eventually give rise to dangerous malignant cells. Whereas many factors may promote the development of these latent cells, others may repress that development. We are now beginning to understand that a wide variety of biochemical and physiological mechanisms may account for these modifier effects.

In the third phase of cell transformation—which does not always take place—the fully developed cancerous cells begin to take on properties that permit transport to, and invasion of, other tissues, a process known as metastasis. This phase has often been described in terms of histological, or tissue, characteristics, although much new information is rapidly becoming available on biochemical and/or biophysical characteristics. Our present knowledge of the effects of nutrients on this third phase is incomplete. Nutrients may or may not affect metastasis.

This three-phase concept is quite useful if we consider how dietary management might be used to repress or prevent the exceedingly complex disease of cancer. In theory, prevention ought to be achievable in either of two ways. The elimination of all dietary initiators is one hypothetical possibility. But since their total elimination is not practical, manipulation of the agents producing cell modification offers a second possibility. When consumed at inappropriate levels of intake, most nutrients tested may act as cell modifiers. In addition to the presence of essential nutrients in foods, there may also be a wide variety of other nonnutrient chemicals such as aflatoxin. Some of these nonnutrient compounds may act as initiators, some may be virtually innocuous, and still others may act as modifiers.

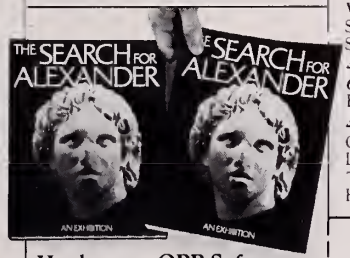
With respect to nutrients, what is an inappropriate level of intake? All nutrients, of course, are required in the human diet at some minimum level in order to satisfy a wide variety of bodily functions. But we are now beginning to recognize that an excessive intake of nutrients may be harmful. When evaluating the effects of nutrients on the risk of cancer, we should attempt to identify the optimum in-

NOW YOU CAN AFFORD TO BUY THE BOOKS YOU WANT TO READ

Tired of today's bookstore prices? Consider the QPB alternative: softcover editions in hardcover sizes that are durably bound and printed on fine paper—but that cost up to 65% less than their hardcover counterparts. QPB. It's the idea whose time has come.

403. How to Doctor Your Feet Without the Doctor. Myles J. Schneider, D.P.M. and Mark D. Sussman, D.P.M. QPB: $7.95

497. The New York Times 60-Minute Gourmet. Pierre Franey Hardcover: $10.95 QPB: $5.95



413. Selling Your Photography: The Complete Marketing, Business, and Legal Guide. Arie Kopelman and Tad Crawford Hardcover: $13.95 QPB Ed: $6.95

402. Fanny: Being the True History of the Adventures of Fanny Hackabout-Jones. Erica Jong Hardcover: $12.95 QPB: $5.50

388. The Woman Warrior and China Men. (2 Vols., Boxed) Maxine Hong Kingston Hardcover: $18.90 QPB Ed: $9.95

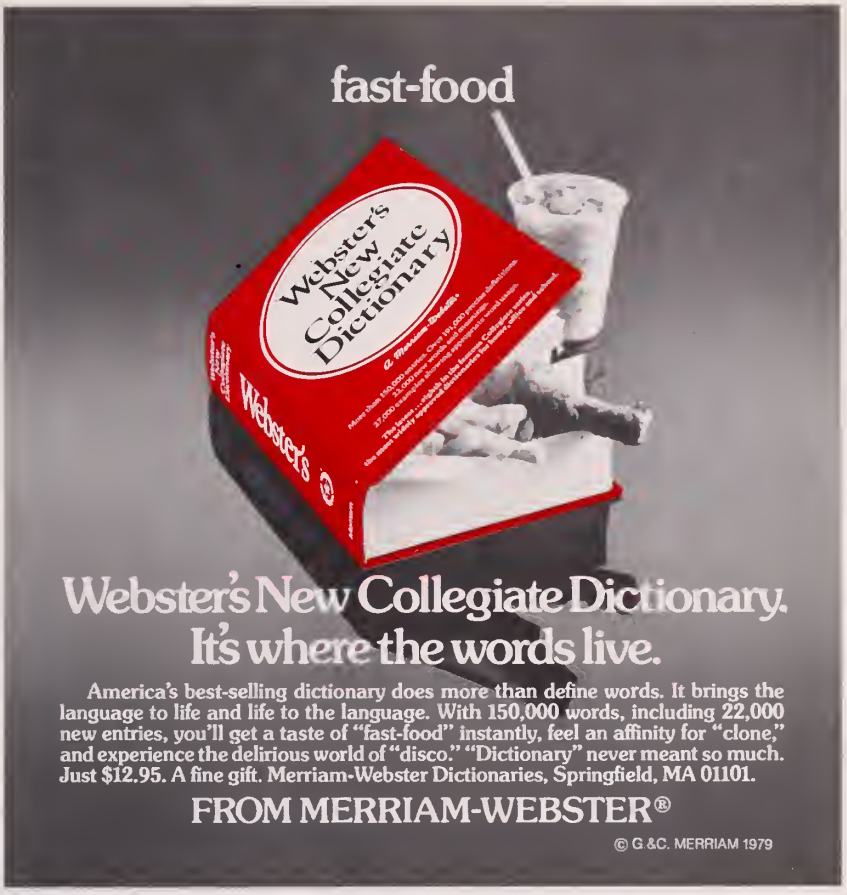
take—within some range—that produces the most beneficial nutritional results while minimizing the risk of cancer. One emerging concept is that those levels that optimize such traditional nutritional effects as healthy growth are the same levels that minimize cancer risk. We now know that inappropriately low intakes of some nutrients may cause an enhancement of the cancer process, whereas with other nutrients inappropriately high intakes may create the same result.

It should be possible to take in nutrients within an optimum range by selecting a wide variety of readily available foods without resort to compensatory gimmicks. This concept, although straightforward, is too often ignored. There have been claims, for example, that unusually high nutrient intakes of selenium and vitamin C are useful in reducing the risk of cancer when, in fact, the experimental observations on which the claims are based were made on much lower levels of intake. More is not necessarily better. (Incidentally, it is important to understand what constitutes an unusually high nutrient intake, or megadose. For some nutrients, including selenium, vitamin A, vitamin D, protein, and linoleic acid [a polyunsaturated fatty acid], an excessive intake may be only a few multiples of the recommended daily allowance, or RDA, established by the Food and Nutrition Board of the U.S. National Academy of Sciences. In the case of other nutrients, including some of the water-soluble vitamins such as all the B vitamins, the difference between the RDA and a potentially toxic dose may be quite large.)

Because nutrients, unlike nonnutrient chemicals, do not act as cancer initiators, we deduce that inappropriate nutrient intakes can modify the carcinogenic process without initiating it. There are numerous mechanisms that appear to account for these nutrient modifications; in fact, each nutrient affecting the carcinogenic process possesses its own set of unique characteristics. Surprisingly, this variety of mechanisms does not necessarily present a hopeless morass in terms of practical information; quite the contrary may be true. The emerging evidence suggests that a few well-chosen dietary practices may serve to simultaneously correct a variety of nutrient imbalances associated with an increased cancer risk. Before discussing such food choices, let us consider a few recently reported examples of nutrient effects that illustrate this concept.

The nutrient, other than dietary fiber, currently receiving the most attention is fat, which has been investigated both in terms of the total amount and the type of fat ingested. In the United States, about 40 to 45 percent of our total caloric intake is supplied by fat. (That compares with 10 to 15 percent for the typical Asian diet.) Several epidemiological studies suggest positive relationships between the total intake of fat and cancer of the large bowel, breast, pancreas, and prostate gland. The early literature on these relationships tended to infer that the higher the total fat intake, the higher the incidence of cancer, with the data for cancer of the large bowel and breast being more comprehensive than the data for pancreatic and prostatic cancer.



More recently, there have been several findings that may permit a finer tuning of that generalization. First, the type of fat appears to be important. Although earlier human population studies indicated a more significant carcinogenic risk with saturated fat (derived largely from animal sources) than for unsaturated fat (from plant sources), later animal model studies did not support this contention. There is now increasing evidence for enhancement of the carcinogenic process by the ingestion of linoleic acid, the only fatty acid that is essential in the human diet. Linoleic acid is present in large amounts in vegetable oils, such as corn oil and safflower oil, where it makes up one-half to three-fourths of the total fatty acids. In addition, animal studies suggest that increasing the intake of linoleic acid increases tumor yield only when there is already a sufficiently high level of total fat. In rats, as with human infants, the requirement for linoleic acid appears to be easily met when that chemical makes up about 0.5 to 1.0 percent of the diet. In the rat studies, where an experimental carcinogenic initiator was given, a diet containing 2.5 percent linoleic acid increased mammary tumor yield only when the total fat content was also high, for example, when fat content represented 12 to 15 percent of the diet by weight, or 25 to 30 percent of the total calories. These effects of linoleic acid and total fat are primarily exerted during the second, or modification, phase of carcinogenesis; that

is, fat promotes the growth and development of already existing cancer cells but does not seem to initiate their formation. Human studies also seem to indicate that a diet high in polyunsaturated fats may present a risk of cancer of the breast and colon.

This emerging understanding of dietary fat illustrates the general concept that although a minimum level of a nutrient is required for good health, an excess may increase the risk of cancer. Another observation made in the above rat studies was that the relationship between linoleic acid and total fat to their carcinogenic effects is not linear as in the generally accepted model for chemical carcinogenic initiators. In short, although increasing fat twofold, fourfold, or eightfold does increase tumors, it doesn't increase them by twofold, fourfold, or eightfold. According to our present knowledge, the relationship differs for each nutrient.

The important message here is that a tumorigenic response is not necessarily exactly proportional to the level of nutrient intake. Also, estimations of cancer risks involving nutrient promoters such as linoleic acid differ from those involving carcinogenic initiators. These initiators do behave in a linear manner, that is, there is a close mathematical relationship between dosage and tumor production. A predictable number of cancer cases in a large population is a hypothetical possibility at low initiator intake levels, thus forcing the need for rigorous and perhaps absolute regulation. In the case of nutrients, not only is absolute regulation impractical but there may be good evidence that carcinogenic risk is near a minimum when the nutrients are consumed within their optimum range of intake.

Other recent data concerning the possible relationship between nutrients and cancer deal with protein, selenium, and vitamin C. To begin with, the effect of protein intake on the carcinogenicity of aflatoxin, which is not a nutrient, illustrates the same concept as that just discussed for linoleic acid. In many species, aflatoxin is a potent initiator of liver cancer, but its total elimination from the human food supply would be impossible without actually banning peanuts, corn, and the wide variety of products derived from them. (Fortunately, there has been excellent progress in this country in lowering the levels of aflatoxin sufficiently to make the sub-

Small Ad for a Big Tour of the Orient

Japan Air Lines has 35 very special tours to the Orient. Come, let us take you to the Orient of your dreams. Here is but one example: Mandarin Orient, 19–24 days, $3197–3675. All tours visit Hong Kong, Peking, Shanghai and Canton. Some tours also visit Tokyo, Penang, Singapore, Bangkok as well as certain cities in China. All tours fully escorted and most meals are included.

Rates based on double occupancy and economy air fare from the West Coast and are subject to change. Additional charge for June–October peak season.

stance of negligible harm.) In rat studies, the carcinogenicity of aflatoxin is decreased when the intake of protein is also decreased. The least carcinogenic effect of aflatoxin appears to occur when protein levels are at or slightly below the recommended dietary allowance. As the level of dietary protein is increased above its requirement, aflatoxin carcinogenicity is also increased, although beyond a certain level of dietary protein (about 20 percent of total diet by weight) there appears to be no further increase. Similar data have also been published in other studies concerning other carcinogens. Once again, the carcinogenic response is most prominent at higher levels of protein intake, with the minimum effect occurring at protein levels near the requirement. In other words, there must be an adequate intake to meet the many needs of the body but not an excessive intake that may increase the risk of cancer. Incidentally, several human epidemiological studies show an extremely impressive positive correlation between dietary protein intake and cancer of the breast, colon, prostate, and pancreas.

Vitamin C (ascorbic acid) is a unique nutrient in that it is required only by primates (including humans), the guinea pig, and a few other, lesser-known species. The daily intake of ascorbic acid recommended for humans is 60 milligrams (recently increased from an RDA of 45 milligrams). The arguments advanced by Linus Pauling that vitamin C prevents the common cold and, perhaps, cancer specify enormous intakes of 10,000 milligrams per day or more. Since it is almost impossible to get more than 1,000 to 1,500 milligrams per day with traditional foods—even those high in ascorbic acid—such megadose effects, if they exist, would have to be regarded as pharmacological rather than nutritional. There is evidence in laboratory studies on rats that vitamin C inhibits gastric and intestinal cancer caused by nitrosamines (compounds derived from the nitrites and nitrates that are added to, as well as found naturally in, certain foods). But adequate protection should be afforded by restricting intake to modest—not megadose—levels. In fact, at very high, or megadose, levels, there is an indication that vitamin C can be mutagenic, which might even suggest a carcinogenic response.

Another nutrient for which inappropriately low or high levels of intake may increase the risk of cancer is selenium. Although the data on this substance need considerably more confirmation, the existing data indicate, once again, that whereas an adequate nutritional intake minimizes cancer risk, more is not necessarily better.

What then is the most appropriate dietary pattern that might allow for simultaneous nutritional benefits? The above-mentioned examples indicate that a diet lower than the current American one in total fat, linoleic acid, and protein, but higher in vitamin C, fiber, and selenium would hypothetically yield the lowest cancer risk. Such a dietary balance can be achieved by an increase in the consumption of whole grain cereal products, vegetables, and fruits, and a reduction in meats and foods prepared in fat. With that regimen, dietary fiber and vitamin C would be increased, while protein and total fat would be decreased. In addition, if less oil were used in cooking, linoleic acid consumption would also be decreased. Selenium intake, however, would not necessarily be altered by such a dietary change. The amount of selenium in a diet is determined primarily by the geographical area from which the food in the diet comes because the amount of selenium available in a particular soil apears to establish the selenium content in the food it yields. Moreover, individual nutrients such as vitamin C, vitamin A, vitamin E, certain amino acids, and polyunsaturated fatty acids may affect the uptake of selenium from the intestinal tract into the bloodstream.

In summary, although it may not be possible to establish the specific effect of the intake of every individual nutrient on the cancer process, the reorientation of diet suggested here should bring about the desired simultaneous alteration of nutrients. Moreover, such a dietary pattern coincides with that recommended for the prevention of cardiovascular disease. Indeed, the same goals should be attained by following the dietary guidelines recently established in the United States by the Department of Agriculture and the Department of Health and Human Services.

T. Colin Campbell is professor of nutritional biochemistry in the Division of Nutritional Sciences at Cornell University in Ithaca, New York, and director of the division's nutrition and cancer program.

Or write for more information.
E. Leitz, Inc., Rockleigh, N.J. 07647.

You wouldn't hang a Picasso in the closet. You'd show it in its best light. Proudly. Leica feels the same way about photography. It would be a pity if pictures taken with our amazing R4 weren't projected with our equally amazing Pradolux* RT300. Each is superb. Together, incomparable.

Consider the Leica* R4, the camera that's so automatic, so responsive, it can do everything, simply. It's the only camera in the world with two independent light meter systems. You can select either full-area (averaging) or selective (spot) metering with a touch of the controls. And you have multi-mode exposure automation working with the two metering systems. Again truly unique. This gives you shutter priority, aperture priority, programmed control, metered manual and flash automation in fractions of a second. And you have a full system of accessories including motor drives and the incomparable Leica-R lenses to bring all this potential to actuality, simply.

The only slide projector made to this high standard is our own: the Pradolux RT300. It offers Leica lenses in a full range from 60 to 200mm in both curved and flat-field configurations. The internal condensers are just as important as the lenses. That's why ours are Leica optical quality, too. You can count on high efficiency cooling for long life of the projector, the lamp and your slides. The Pradolux RT300 accepts Kodak Carousel* trays and stack loaders. Plus a range of built-in features that seems to go on forever.

*Trademark Eastman Kodak Company.

In fact, with both the Leica R4 camera and Pradolux RT300 slide projector you will see how impressive your images really are, Pablo. Ask your full-line Leica dealer for information; he's listed in the adjacent column.

Leitz

Leitz means precison. Worldwide.

THE LUXURY SEDAN THAT DID NOT HAVE TO BE RE-ENGINEERED TO FACE DIFFICULT TIMES.

Will the trials and tribulations of the automobile industry never end?

First came the Environmental Protection Agency and the need to re-engineer to meet the emission requirements.

Then came the gas crises and the need to re-engineer to meet the demands of the gas pump.

Then came last year's money crunch and the most serious challenge of all: the enlightened consumer.

And, with a certain predictability, the luxury sedan makers of the world reacted by bringing forth a slew of "revolutionary" new automobiles, each radically re-engineered to answer the perfectly reasonable question, "What is it that makes an expensive car worth the money?"

A question perhaps uniquely answered by the BMW 528i.

TECHNOLOGY DECADES AHEAD OF THE COMPETITION.

As some of the world's most exalted automobile manufacturers rush to update anachronistic technology—cutting cylinders, resorting to diesel fuel, tinkering with all manner of electronic gadgetry—one caveat should be observed: evolution, as any automotive expert will testify, is always far preferable to revolution. We are, after all, dealing with a machine made up of several thousand parts.

Which is perhaps the most convincing argument for owning the BMW 528i. A car developed and refined over two decades. An engineering concept so basically sound that an era of automotive restrictions has, if anything, proven it to be even more correct.

A SYNERGISTIC USE OF ELECTRONICS AND MECHANICS.

Car and Driver magazine has seen fit to predict, "In the not-too-distant future, most cars will be equipped with some form of electronic fuel injection simply because it is a more precise fuel-delivery system."

Far from just beginning to dabble in the sophisticated arena of electronics, BMW installed such a system in 1975.

With every engine revolution a computer receives and assesses signals from electronic sensors within the 6-cylinder engine itself. Then instantly determines the precise air/fuel mixture to be injected into the cylinder ports—optimizing emissions, fuel consumption and power development to a degree once considered merely within the realm of academic theory*

So flawless is this marriage of electronics and mechanics that it has resulted in a virtual automotive paradox: an engine which not only performs with more fuel efficiency but with more power as well.

THE DRIVER COMPLETES THE MECHANICAL CIRCUIT.

The interior of the 528i, while classically restrained in style, denies its occupants nothing with regard to appointments or accessories.

But, perhaps because of our involvement with motor racing, we take a wholly different approach to the interior of an automobile.

An approach which includes the driver as a functioning part of the car.

A standard 5-speed transmission (automatic is available) affords the unaccountably unique opportunity to pick and choose one's own gears.

An advanced suspension system—independent on all four wheels—provides what one automotive journalist hailed as "a confidence-inspiring stability." Giving the driver an uncanny feel for the road.

EXTRAORDINARY ENGINEERING IS AN EXTRAORDINARY INVESTMENT.

BMW has always contended that only one thing makes an expensive car worth the money: Extraordinary engineering.

The BMW 528i has itself turned that contention into fact.

For, according to the Oct. 1980 NADA Used-Car Guide, over the past 5 years, the 5 Series has retained an astonishing 77.9% of its original price.

A figure which neither the Mercedes 280E, nor the Jaguar XJ6, nor Cadillac can approach.

If you find the notion of owning a BMW intriguing, phone your nearest BMW dealer and arrange a thorough test drive.

THE ULTIMATE DRIVING MACHINE.

BMW. MUNICH GERMANY

*For example, the BMW 528i (with 5-speed standard transmission) delivers 18 EPA estimated mpg, 30 estimated highway mileage and, based on these figures, an estimated mpg range of 295 mi. and a highway range of 492 mi. (Naturally, our fuel efficiency figures are for comparison purposes only. Your actual mpg and range may vary, depending on speed, weather and trip length. Your actual highway mileage and highway range will most likely be lower.) © 1981 BMW of North America, Inc. The BMW trademark and logo are registered trademarks of Bayerische Motoren Werke A.G.

The Titular Bishop of Titiopolis

The posing of a problem in a novel way is a virtual prerequisite of great science

by Stephen Jay Gould

Modern geology began, or so the usual story goes, with the publication of a book so oddly named that it almost surpasses the peculiarity of the title later assumed by its author, Nicolaus Steno, a Dane by birth and a Catholic convert who became Titular Bishop of Titiopolis (*in partibus infidelium*) in 1677. (Titular bishops "preside" over areas in pagan hands and therefore unavailable for actual residence—in the realm of infidels, as the Latin subtitle proclaims. The old bishopric of Titiopolis is now part of Turkey.) As his real job, dangerous enough in Protestant lands, Steno ministered to the scattered Catholic remnants of northern Germany, Norway, and Denmark.

The book, published in 1669, bears a title considered "almost unintelligible" by its chief translator from the original Latin. It is called *De solido intra solidum naturaliter contento dissertationis prodromus,* or *Prodromus to a dissertation on a solid body naturally contained within a solid.* A prodromus is an introductory discourse, but Steno never wrote the promised dissertation because his religious interests, following his conversion in 1667 and his ordination in 1675, led him to abandon his distinguished scientific career as a medical anatomist and, by fortuitous introduction at the very end of his scientific work, a geologist.

Why a solid within a solid? And what can such a cryptic phrase have to do with the origin of modern geology? Posing a problem in a startling and novel way is the virtual prerequisite of great science. Steno's genius lay in recognizing that a solution to the general problem of how solid bodies get inside other solids might provide a criterion for unraveling the earth's structure and history. But Steno did not formulate his problem by rational deduction from his armchair. As so often happens in a human world, he drifted toward it after an accidental beginning.

Like many anatomists, Steno became interested in the resemblances of humans to other animals. He decided to dissect sharks and made some important discoveries. He demonstrated, for example, that the tight coils of the spiral intestine yielded the same total length (within a more confined space) as the meandering intestine of mammals. In October 1666, during Newton's great year, or *annus mirabilis,* and a month after London burned, Steno received for study the head of a giant shark caught at the city whose English name Leghorn is as peculiar as Steno's two titles. (The name refers neither to limbs nor musical instruments, but represents a poor English rendering of the old spelling, Ligorno, for the town now called Livorno in Italian.) Steno, like so many intellectuals, was working at the nearby city of Florence under the patronage of Ferdinand II, the Medici grand duke. In examining the teeth of his quarry, Steno recognized that he had accidentally bought into one of the major scientific debates of his age, the origin of *glossipetrae,* or tongue stones.

These fossil sharks' teeth could be collected by the barrel, especially in Malta. In twentieth-century terms, their origin cannot be doubted. They are identical to the teeth of modern sharks in outward form and detailed structure and chemical composition—therefore they cannot be anything but sharks' teeth. (Even our antediluvian creationists today do not deny it.)

Yet the identity in form that makes us so certain led to another potential interpretation in Steno's time—for God, the author of all things, often created with striking similarity in different realms to display the order of his thoughts and the glorious harmony of his world. If he had made a world with seven planets (sun, moon, and the five visible planets of an older cosmology) and seven notes in a musical scale, why not imbue rocks with the plastic power to form objects precisely like the parts of animals? After all, the *glossipetrae* came from rocks and rocks were created as we find them. If the tongue stones are sharks' teeth, how did they get *inside* rocks? Moreover, the earth is only a few thousand years old, and tongue stones inundated European collections. How many sharks could have infested Mediterranean waters in so short a time?

Steno observed that his shark had hundreds of teeth and that new ones formed continually as old teeth wore

Take the $81.80 Library of Ancient Civilizations for only $2.97

when you join the **Natural Science Book Club.** You simply agree to buy 3 more books—at handsome discounts—within the next 12 months.

Here's a fantastic opportunity to get this beautiful $81.80 set of 4 oversized volumes for only $2.97. Together they present a fascinating view of the development of mankind.

THE ARCHAEOLOGY OF GREECE. William R. Biers. A splendidly illustrated volume presents a historical and artistic summary of ancient Greek culture. Traces the stylistic developments in architecture, sculpture, painting and other art forms. With 106 drawings, 334 photographs, 8 pages of color plates. Publisher's Price $29.95

ANCIENT EGYPT, THREE THOUSAND YEARS OF SPLENDOR. Warner Hutchinson. Provides a fascinating tour of the Nile, Egyptian life styles, and the reasons why Egypt rose to such heights in the ancient world. Contains over 125 photographs of wall paintings, architecture and statuettes. Publisher's Price $16.95

STONEHENGE AND ITS MYSTERIES. Michael Balfour. 200 diagrams, maps, charts and striking photographs combined with authoritative text reveal both the facts and mysteries of Stonehenge. Shows how artists, politicians, astronomers and the public have viewed Stonehenge through the ages. Also discusses other nearby prehistoric sites. Publisher's Price $14.95

THE MAYA. 2nd Edition. Michael Coe. Newly revised classic presents every stage of the 3000-year rise and fall of the New World's most advanced civilization. Explores in detail the Mayan life cycle, their stunning art, inscrutable hieroglyphs, the building of palaces, temples and pyramids, the intricate Mayan calendar and much more. With 141 illustrations. Publisher's Price $19.95

What is the Natural Science Book Club? A unique book club devoted to bringing you exciting, refreshingly different books on all areas of the natural sciences. From the life story of early man to the death of the solar system... from the largest mammals to the invisible kingdom of microscopic organisms... all the wonders of the natural world are revealed to members of the Natural Science Book Club.

MEMBERSHIP BENEFITS • In addition to getting the Library of Ancient Civilizations for only $2.97 when you join, you keep saving substantially on the books you buy. • Also, you will immediately become eligible to participate in our Bonus Book Plan, with savings of at least 70% off the publisher's prices. • At 3–4 week intervals (16 times per year) you will receive the Book Club News, describing the coming Main Selection and Alternate Selections, together with a dated reply card. • If you want the Main Selection, do nothing and it will be sent to you automatically. • If you prefer another selection, or no book at all, simply indicate your choice on the card, and return it by the date specified. • You will have at least 10 days to decide. If, because of late mail delivery of the News, you should receive a book you do not want, we guarantee return postage.

Natural Science Book Club
Riverside, New Jersey 08075 4-AL7

Please accept my application for trial membership and send me the Library of Ancient Civilizations A(10106), billing me only $2.97. I agree to purchase at least three additional Selections or Alternates over the next 12 months. Savings range up to 30% and occasionally even more. My membership is cancelable any time after I buy these three books. A shipping and handling charge is added to all shipments.

No-Risk Guarantee: If you are not satisfied—for any reason—you may return your introductory books within 10 days and your membership will be canceled and you will owe nothing.

down and fell out. The numbers of *glossipetrae* from Malta no longer foreclosed an origin in sharks' mouths, even under the Mosaic chronology (which Steno did not question). According to the common legend that great scientists are unprejudiced observers who can shuck constraints of culture and see nature directly, Steno came to his correct conclusion—that *glossipetrae* are fossil sharks' teeth—because he made better observations. Steno was a fine observer, but he was also an adherent to the new mechanical philosophy that insisted on physical causes for phenomena and viewed detailed internal similarity as a sure sign of common manufacture in the mechanical sense. Steno did not see better; rather, he possessed the conceptual tools to interpret his excellent observations in a necessary way that we continue to regard as true.

But Steno then abstracted the problem of *glossipetrae* in a remarkably original manner—and established with this great insight his legitimate role as the founder of modern geology. The tongue stones found within rocks, Steno reasoned, were problematic because they were solids enclosed within a solid body. How did they get in there? Steno then recognized that all the troubling objects of geology were solids within solids—fossils in strata, crystals in rocks, even strata themselves in basins of deposition. A general theory for the origin of solids within solids could provide a guide for understanding the earth's history.

Taxonomy is often regarded as the dullest of subjects, fit only for mindless ordering and sometimes denigrated within science as mere "stamp collecting" (a designation that this former philatelist deeply resents). If systems of classification were neutral hatracks for hanging the facts of the world, this disdain might be justified. But classifications both reflect and direct our thinking. The way we order represents the way we think. Historical changes in classification are the fossilized indicators of conceptual revolutions.

The French scholar Michel Foucault uses this principle as his key for understanding the history of thought. In *Madness and Civilization*, for example, he notes that a new method of dealing with the insane arose in the mid-seventeenth century and spread rapidly throughout Europe. Previously, madmen had been exiled or tolerated and allowed to wander about. In the mid-seventeenth century, they were confined in institutions along with the indigent and unemployed, a motley assemblage by modern standards. We might regard this classification as senseless or cruel, but as Foucault argues, such a judgment will not help us to understand the seventeenth century.

Why classify together the poor, the unemployed, and the insane; what common theme could inspire such an ordering? Foucault argues that the birth of modern commercial society led to a new designation of the cardinal sin, the one that had to be made invisible by confining all those who, for whatever reason, wallowed in it. That sin was idleness, and Foucault shows that sloth replaced the old medieval curse of pride as the most fundamental of the seven deadly sins in seventeenth-century texts. It mattered little that the insane did not work for biological or psychological reasons, and the unemployed for want of opportunity.

Steno also reordered the world in a way that must have seemed as curious to his contemporaries as the amalgamation of madness and poverty seems to us. As his contemporaries gathered the idle, Steno identified solids within solids as a fundamental class of objects, divided them from everything else, and developed a set of criteria to sort his solids into subdivisions representing the different causes that fashioned them. The great *Prodromus* is, fundamentally, a treatise on a new system of classification for solids within solids—a classification by common genesis, rather than superficial similarity of outward appearance. Steno's revolution in thought arises from his altered classification—and his curious title, so understood, could not be more devastatingly appropriate. I have read the *Prodromus* many times, but when I finally understood its message, just last month, that bizarre title sent a shiver up my spine.

The *Prodromus* has usually been misinterpreted by geologists who attribute Steno's success to his use of modern observational methods. (In fact, although the *Prodromus* is sprinkled with astute observations, its longest section is a speculative discussion on the origin of solid bodies, based on the incorrect premise that all solids must be generated from liquids, and that the form of a solid indicates the motions of the liquids that produced it.) His translator writes, for example:

"At a time when fantastic metaphysics were rife, Steno trusted only to induction based upon experiment and observation." But the *Prodromus* reports no real experiments and only a modest number of observations. It succeeded primarily because Steno followed a metaphysic congenial with our own, but relatively new in his time.

Geologists have also judged Steno inappropriately by searching the text for gems of "modern" insight, rather than by understanding its argument as a totality. Thus, the commonest statement about the *Prodromus,* often the only statement made by geologists, holds that Steno presented the crystallographic law of the constancy of interfacial angles—that however much the size and shape of crystal faces vary, the angles between them remain the same. Well, perhaps he did, but the "law" appears as two throwaway lines in a figure caption, and has little relation to Steno's major theme or argument. (It arises simply as a corollary to his speculations about inferring the motion of fluids from the form of solids precipitated from them.)

No, the *Prodromus* is, as its title states, about solids in solids and their proper classification by mode of origin. It is founded upon two great taxonomic insights: first, the basic recognition of solids within solids as a coherent category for study and, second, the establishment of subdivisions to arrange solids within solids according to the causes that fashioned them.

Steno uses two criteria for his subdivisions. (They are blessedly obvious once you state the problem, but Steno's revolution is the statement itself.) First, in what might be called the principle of molding, Steno argues that when one solid lies within another, we can tell which hardened first by noting the impress of one object upon the other. Thus, fossil shells were solid before the strata that entomb them because shells press their form into surrounding sediments just as we make footprints in wet sand. But surrounding rocks were solid before the calcite veins that run through them because the calcite fills preexisting channelways just as jello matches the flutes of a mold. The principle of molding allows us to establish the temporal order of formation for two objects in contact. In a world still regarded by many of Steno's contemporaries as formed all at once by divine fiat, this criterion of history struck a jarring

Get the Lion's share!

High yields. Plus

Daily dividends!
Daily compounding!
Daily liquidity!

You get all this when you invest in Dreyfus Liquid Assets, the high yielding money market fund:

Dividends are declared and compounded daily. You get free checks for cash as you need it, or to pay larger bills. And you keep on earning today's high money market yields until your redemption check clears.

There is no sales charge, there's no penalty for early withdrawals--you can even redeem your investment by phone. Start with just $2,500. Additions can be as low as $100.

chord and eventually forced a transposition in thought.

Early in the *Prodromus*, Steno stated the problem that he wished to solve with his second criterion: "Given a substance possessed of a certain figure, and produced according to the laws of nature, to find in the substance itself evidences disclosing the place and manner of its production." His solution, the basic principle for any historical reconstruction, holds:

> If a solid substance is in every way like another solid substance, not only as regards the conditions of surface, but also as regards the inner arrangement of parts and particles, it will also be like it as regards the manner and place of production.

Past processes cannot be observed in principle; only their results remain. If we wish to infer the processes that formed any geological object, we must find clues in the object itself. The surest clue is detailed similarity—part by internal part—with modern objects formed by processes we can observe directly. Similarity can be misleading—and great mistakes have been made in applying Steno's principle—but our confidence in common origin mounts as we catalog more and more detailed similarities involving internal structure and chemical composition as well as external form.

Thus, Steno argues, sedimentary rocks must be the deposits of rivers, lakes, and oceans because they "agree with those strata which turbid water deposits." Fossil shells once belonged to animals, and crystals precipitated from fluids as we make salt or rock candy today.

With these two principles—molding and sufficient similarity—Steno established both prerequisites for geological, or any historical, reconstruction: he could determine how and where objects formed, and he could order events in time. Steno's genius, to say it one more time, lay in establishing this new conceptual framework for observation, not in the acuity of the subsequent observations themselves. Steno's break with older traditions stands out most clearly in his complete failure, save in one sheepish passage, to consider the primary subject that obsessed his colleagues: the identification of goals and purposes for all things, including what we now regard as purely physical processes of uplift, erosion, and crystallization. In one fleeting passage, Steno cites dissimilarity of function as a reason subservient to his usual argument about internal resemblance for stating that rocks and bones form differently. But he quickly adds the disclaimer, "if one may be permitted to affirm aught about a subject otherwise so little known as are the functions of things." As Foucault also argues, the subjects you leave out of your taxonomies are as significant as the ones you put in.

The four-part organization of the *Prodromus* has generally been viewed as disjointed or even incoherent—thrown together by a man itching to leave Florence but forced to justify the grand duke's patronage. I view it instead as a comprehensive and tightly reasoned brief for a science of geology based upon the two principles of molding and sufficient similarity.

Part one is a teaser, a specific example to demonstrate the power of the general method. The *glossipetrae*, Steno argues, must be sharks' teeth because they are identical in form and internal arrangement with the objects he had plucked from the mouth of his quarry from Leghorn. They solidified before the rocks that enclose them because they impress their form upon the surrounding sediment. Therefore—and now the argument begins to move toward revolutionary generality—sedimentary rocks were not created with the earth, but have formed as the deposits of turbid waters in rivers, lakes, or oceans. Moreover, similar marine fossils are often found high in mountains and far from the sea; these fossils also solidified before the strata enclosing them. Thus, the earth has an extensive history: seas and lands have changed places, and mountains have emerged from the waters.

In the second part, Steno argues that *glossipetrae* are but one example of the general problem of solids within solids, and that the principles of molding and sufficient similarity can establish proper taxonomic subdivisions based on common modes of origin. The third part treats the major classes of solids within solids and establishes two basic categories for objects within rocks: fossils that harden *before* the enclosing strata, and crystals and veins that form *within* solid rocks.

The fourth part, a reconstruction of the geological history of Tuscany, has been problematic or even embarrassing to geologists who wish to view Steno as their founding saint. (The Catholic Church, by the way, is also considering Steno for sainthood, and he may eventually attain an unprecedented double distinction.) Steno constructs his history to match biblical chronology, with two cycles of deposition—from the original void and from Noah's universal ocean. The essence of this part, however, is not his continued loyalty to Moses—Steno was, after all, not a man of our century—but rather his demonstration that the principles of molding and sufficient similarity can be used not only to classify objects (part three), but also to reconstruct the history of the earth from these objects (part four). The last part of the *Prodromus* demonstrates by specific example, drawn from the local terrain, that the proper classification of solids within solids can establish a science of geology.

In 1678, Athanasius Kircher published a figure showing all letters of the alphabet, including the contraction Æ, etched in veins of calcite. Today, we chuckle and dismiss the well-formed letters as accidents. But to Kircher they were no less significant than the shells of clams also found in rocks. One might argue that clams are more complex than letters, but a Venetian work of 1708 depicted an agate that seemed to show, in its bands of color, Christ on the cross with all proper accouterments, including a sun on the favored right side and a moon on the despised left. The caption proclaimed in German doggerel: *Solche wunderbarliche Gestalt, hat die Natur in ein Agat gemahlt*—"Nature herself has painted this wonderful figure in an agate." Why was a clam in a rock different from a letter or a crucifixion? Since alphabets and religious scenes cannot be preexisting objects buried in strata, they must be made by a plastic power in the rocks themselves. As long as "odd things in rocks" formed a single category, clams and sharks' teeth would also be manifestations of the plastic force and no science of paleontology or of historical geology would be possible. But Steno's classification recognized the basic distinction between fossils that hardened before the rocks that enclosed them and intruding veins that might by accident resemble some abstract form or design.

Steno changed the world in the simplest and yet most profound way. He classified its objects differently.

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

What your home could have in common with the Met, the Tate, and the Louvre

Roberto Crabani's *Alla Stazione*, original lithograph. Signed limited edition of 175

Marc Chagall's *Le Tres Beau*, original lithograph. Signed limited edition of 50

Shimotakahara's *Green Tree Study*, original serigraph. Signed limited edition of 150

Johnny Friedlaender's *Verbatim*, original etching. Signed limited edition of 95

In your own home, you can exhibit original work by artists who are represented in the world's great museums and galleries.

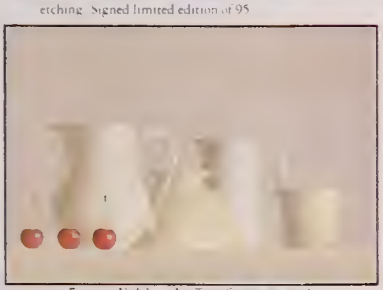
Artists like Calder. Chagall. Dali. Miró. Picasso. Vasarely.

At the Original Print Collectors Group, we offer moderately priced limited edition prints by these and other well-known artists.

Our offerings include signed original etchings, engravings, and silk-screen prints.

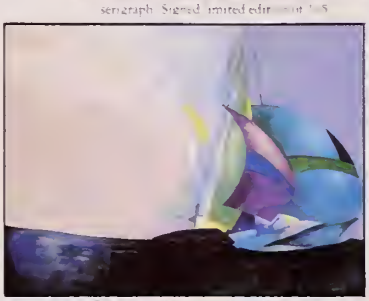
Each print we offer is signed and numbered by the artist. Custom-framed. Accompanied by a certificate of authenticity and a full money-back guarantee.

And each print has been chosen not only for its beauty but for its investment value.



(Works by the artists we offer tend to appreciate, sometimes as much as 30% in a single year. Perhaps that's why *The Wall Street Journal*, *Business Week*, *Money*, AP, *Barron's* and UPI have quoted us as an authority on investing in art.)

For more information, send in the coupon. There's no obligation.



You'll find out about the special pleasure of owning original art, instead of just visiting it.

Artist's Pe... "Window", original serigraph. Signed, limited edition of 165

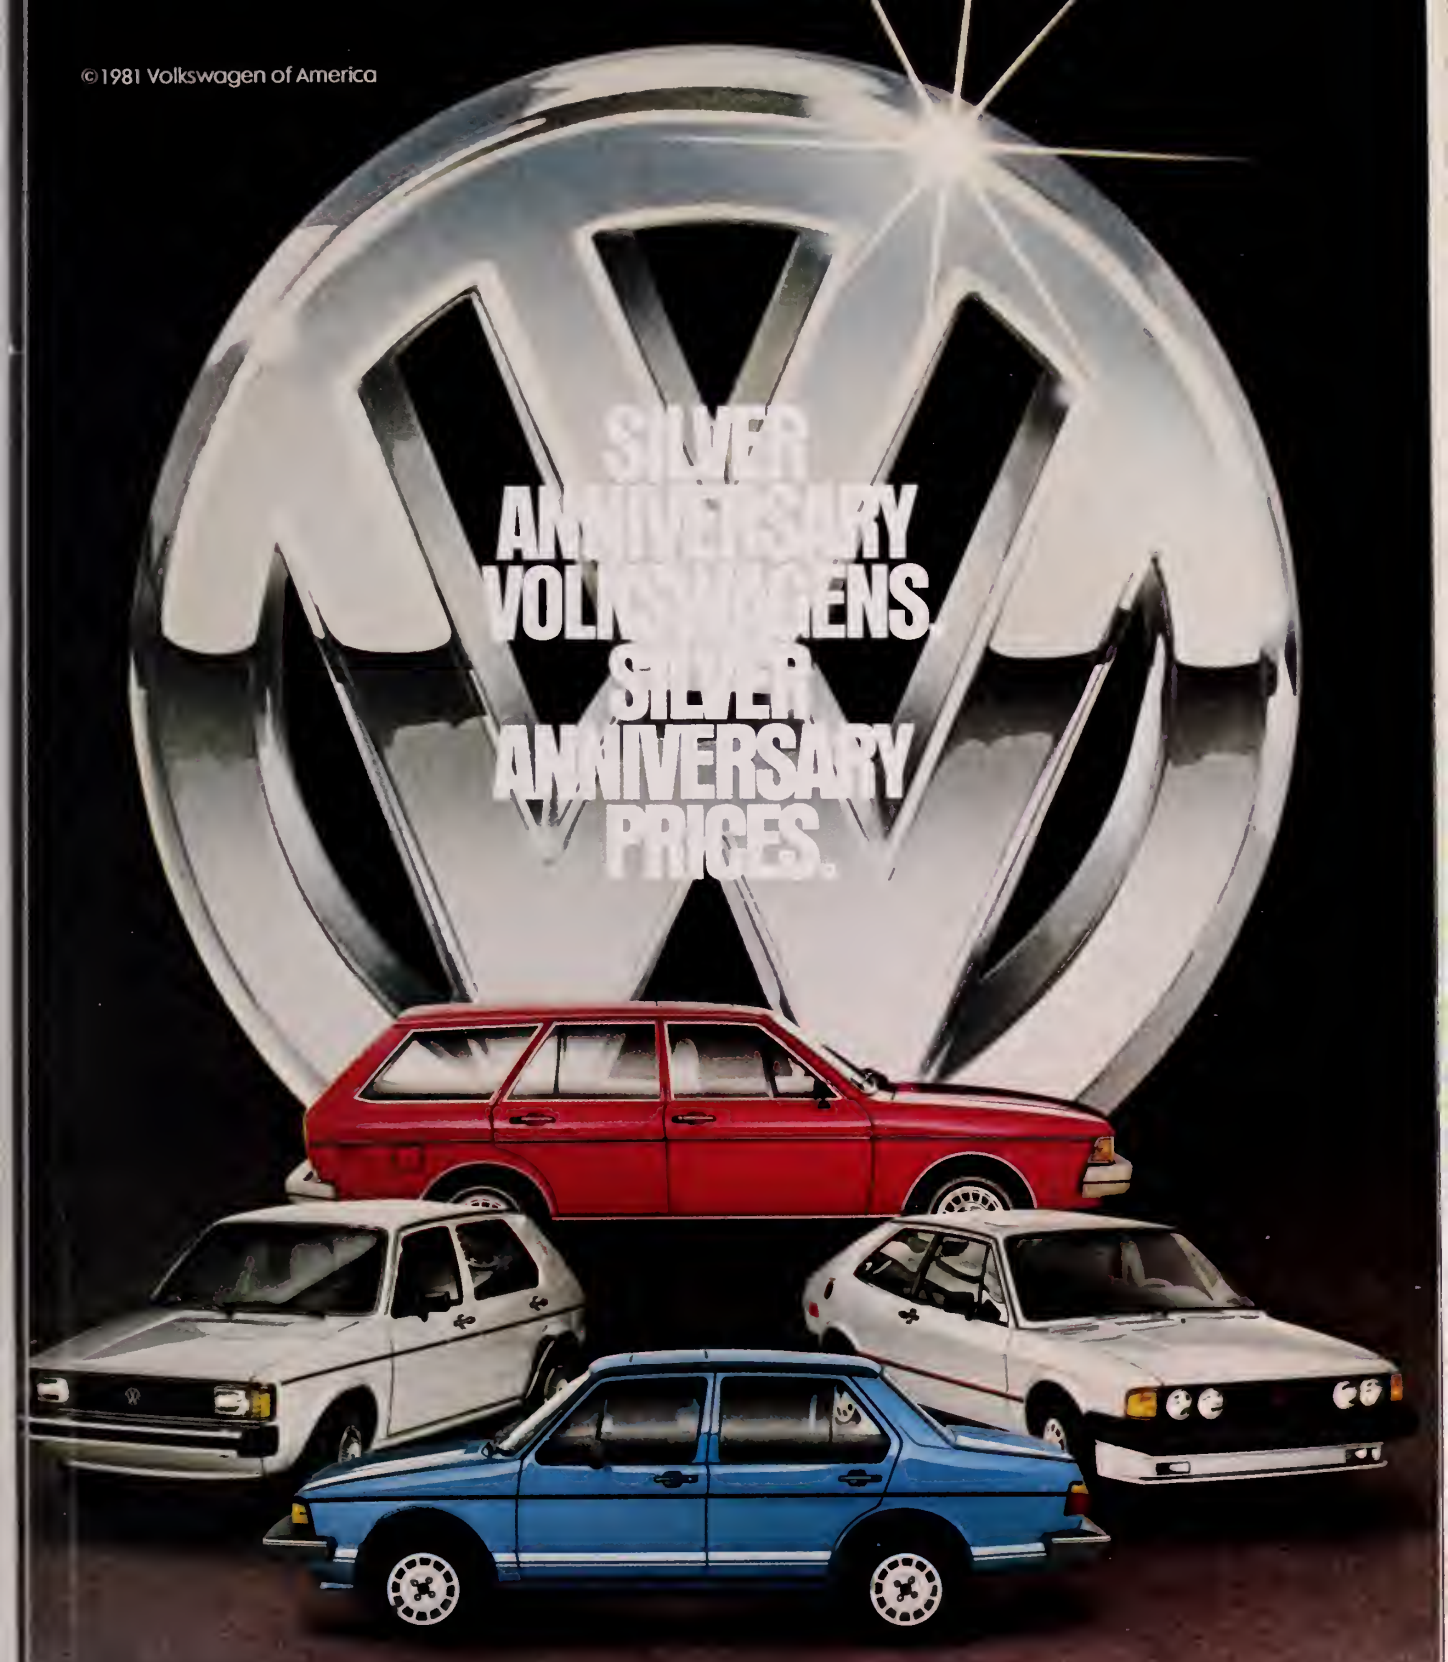
East African Safari

The quarry may be a lost identity that cannot be found in game parks

by Colin Turnbull

What is there about East Africa that drives thousands of tourists every year from comfortable homes in Japan, the Americas, and Europe and sends them flooding to Nairobi? What is it that transcends the cultural differences that these groups often seem to wish to exaggerate, rather than conceal, and gives them all the same air of expectancy and hope? And what is it that for many of them brings ultimate disappointment?



The search for an answer leads in many unexpected directions and shows how much the tourist is underestimated; how even when avowedly seeking escape, relaxation, and "fun," the tourist may be a pilgrim in search of something far greater. Some tourists deny this, insisting on their hedonism; others suspect the truth and are made uncomfortable, for the thought means that they may not, after all, have gotten what they came and paid for. The streets and hotels and bars of Nairobi are full of tourists, as are the cocktail lounges of every safari lodge. In one morning, in Barclay's Bank on Kenyatta Avenue, I met enough tourists to fill a book. They all had the same stated objectives: to see the animals, to see Africa, to see Mount Kilimanjaro. Since one would have to be blind not to see all of these things within twenty-four hours of arrival if desired, how is it possible to meet so many disillusioned tourists in one morning in one bank?

During a one-hour period I met two young French tourists who had abandoned their three-week safari after six days and were returning to Paris "because it is all too artificial . . . like an animated picture postcard"; a British couple who complained that "things are more natural and a bloody sight cheaper on the Yorkshire moors"; and a group of Californians who were already planning next year's holiday at Disneyland. It was difficult to find a tourist who did not suffer some disappointment, although it was often concealed beneath loudly voiced complaints directed at frustrating bank procedures or under enthusiastic comment on the grandeur of the scenery and the quantity of wildlife seen. There was plainly something lacking in the *quality* of the experience. One Frenchman said he had expected something more alive, more vital. The British couple kept harping on the "holiday camp" atmosphere and on human interference with nature. The Californians, interestingly, said they expected to find Disneyland both more "real" and more "natural."

There is, of course, something ironic in the very supposition that a game park is natural in any way. And the reference to Disneyland alerts us to the problem of separating most people's conception of reality from fantasy, which is often more powerful than empirical reality. Perhaps these tourists missed what they sought because they came prepared to rely primarily on one sense alone, that of sight. The came to *see* animals, Africa, and Kilimanjaro, and that is what they had accomplished. When I asked them what they had smelled, they were affronted. When I asked what they had heard, they recounted gossip, political comment, and barroom stories. And when I asked what they had touched, they considered the question too stupid to answer. Their awareness might have been greater had they been blind, for then they would have been forced to use their other senses, to interpret their own experience through the eyes of others. But at least they knew they had missed something.

Governmental policies and travel agencies are partly to blame. Thanks to lavish brochures and color posters, most tourists have "seen" it all long before they set out. The main difference is that in real life the game moves, the waterfalls fall, and the dancers jump and gyrate. In East Africa, the brochure is animated. The experience is like looking at a familiar home movie, sharing it with a large audience of other tourists seated in clusters of Land Rovers, minivans, and air-conditioned coaches. Governmental sensititivy to Africa's tribal past adds to the sense of artificiality and disappointment. Taking their cue from the West, most African governments equate tribalism and tradition with "backwardness." Yet, knowing the appeal of the so-called primitive, the same governments perpetuate the very myth of the backward native that they wish to dispel. Here we get a glimpse of some of the enormously powerful side effects of tourism, of its impact on governmental policy and the lives and welfare of whole populations. To satisfy the tourist demand for tangible evidence of Africa, the gift shops and boutiques are filled with tawdry trinkets that even at the most expensive best only barely resemble the greatness of a lost tradition. "Traditional" dances are staged that are a travesty

Better get to a Volkswagen dealer like quicksilver. We're celebrating 25 years of being Volkswagen in America. In this festive mood, we're offering silver anniversary prices and deals on all our silver anniversary Volkswagens. Rabbit. Dasher. Scirocco. Jetta. Vanagon. And our super sporty Pickup. What a time to buy a Volkswagen. The price of silver may never be better.

VOLKSWAGEN CELEBRATES 25 YEARS OF BEING VOLKSWAGEN IN AMERICA.

Very easy to take.

HOPEWELL ROCKS, NEW BRUNSWICK

CAVENDISH, PRINCE EDWARD ISLAND

STEWIACKE RIVER, NOVA SCOTIA

WESTERN BROOK GORGE, NEWFOUNDLAND

Your family vacation in Canada's Atlantic provinces is very easy to take, for all kinds of very good reasons.

You are in easy driving distance of our provinces-by-the-sea. And when you cross our friendly border you'll find the roads a lot less crowded.

Or you can fly here. There are major airports in each of the four provinces with national car rentals available at each terminal. Or you can take the ferry. Drive aboard at Portland or Bar Harbor, Maine.

You'll quickly discover why people keep coming back.

Clean, fresh air and miles of uncrowded beaches. The kind of scenery that keeps cameras clicking, majestic highlands and rolling farmlands; silent fiords and tranquil fishing villages. And for a change of pace, sample city life as we live it. Remember, each of the four provinces also offers its own, unique attractions.

You can eat the freshest foods from land and sea. Spend your nights in a farmhouse, or snug in a home by the wave-washed shore. You can bring your tent or trailer, or take your pick from motels, hotels and fine resorts. You will also find your U.S. dollars are worth a whole lot more in Canada. Which means big savings on accommodation, meals, shopping and transportation.

You can swim, sail, golf, play tennis, fish; you can browse around, go to the theatre; or simply sit back and relax, knowing you are always welcome.

This vacation, come to Canada's Atlantic provinces. Very easy to take, but very hard to forget.

of all that dance used to be in African society. Once an integral and vital part of African social, religious, and political life, dance is now an empty mockery, choreographed to fit the limited floor space of a nightclub, gaudily costumed to satisfy a concept of propriety, new to Africa, that the West is fast leaving behind.

Most of the tourists I met clarified "seeing Africa" as *meeting* Africans, although some still insisted that they only wanted to *see* the people. But what Africans do most tourists see, other than hotel and tour employees or the costumed dancers, who are entertaining but quite unbelievable? They see Africans smartly dressed in Western-tailored clothing, sporting Western manners and Western speech. To many that is almost as unbelievable as the costumed dancers, and again they suspect artificiality. In any case, that Africa, clothed by Saville Row, is not what they came so far to see. "We thought it would be more primitive" is a frequently heard comment. It is an innocent observation, devoid of insult; for many, *primitive* conveys not so much backwardness as some kind of primal truth, referring to a state when man and nature lived in harmony, rather than locked in combat.

The Yorkshire moors may or may not be more natural than an East African game park, but clearly the English couple, and others like them, came searching for some kind of primal truth they had sensed elsewhere. The government and tourist agencies, however, make it next to impossible for average tourists to make effective contact with the Africa they hope to find. Motivated in part by considerations of image and financial profit, the agencies discourage the individual or family holiday on which it was once possible to drive freely across the African countryside, camping by the roadside, accepting the friendly and uncontrived hospitality of Africans in their rural villages, learning about Africa from them, seeing it as they see it, with their senses and sensitivity. Today it is almost impossible to avoid the organized group safari that leads the tourist from one air-conditioned luxury lodge to another, often providing a guaranteed "photographic bag" of every major form of game. Some safari lodges arrange for early morning wake-up calls as soon as the tourist's selected prey has obligingly presented itself for viewing from the

hotel veranda, to be served up with morning coffee or tea, so to speak. All but the most devoted animal watchers are easily distracted by the drinks-while-you-wait approach. Indeed, many are sidetracked into using the photographic safari as an excuse for dressing up in safari suits and participating in a well-staged colonial period piece in which man is the hunter and the animals his prey. Moreover, the "natives" are guaranteed to be suitably subordinate.

In Nairobi, my colleague and I, both knowing East Africa well from many previous visits, attempted as tourists of moderate means to arrange a simple holiday that would avoid the luxury route and the organized group tours. No fewer than six safari firms said it was impossible. What they meant, of course, was that it would not be worth their while. We finally found a firm that booked us first into a do-it-yourself lodge in a game park and then into a tent camp by a bird sanctuary. Both were easily reached in a small rented car. The lodge, consisting of half a dozen separate furnished bungalows, was almost totally deserted during our week's stay. A mile away, in the same game park, the luxury hotel was full. From the open veranda of our small bungalow we saw every kind of game, mostly but by no means exclusively on the far side of a crocodile-filled stream, which ran through a gully fifty yards away. In fact, we saw more animals there than we did driving through the park, where other tourists were more prominent than the game. A park employee visited the lodge daily to make sure we had drinking water and kerosene for cooking. When off duty he accompanied us to a local market and introduced us to a variety of local foods, including some cooked in his own home. And he talked about his country and his people.

The tent camp was not such a success, consisting of a score or so of shabby tents, pitched under trees on the lawn of a hotel by the shores of a lake. The bedding was musty and damp, the mosquito netting torn, and the tents filled with every imaginable kind of insect. Toilets and bathrooms located behind the tents were barely usable. Only one other tent was occupied and that only temporarily and unofficially by amorous couples at night. Everything seemed designed to give us cause for complaint, and complaint was met by the European manager with the offhand suggestion that, if we did not like it, we could always move into the more expensive hotel, which she also ran. Thus, either by a systematic lack of publicity or by an equally systematic program of mismanagement, tourists are discouraged from going off on their own and are compelled to accept what is given. The individual safari, on which Africa can indeed be seen, is still possible but it takes a good deal of time and money. The average tourists—confined to the safari circuit and organized groups—are carefully kept at a distance from all that they observe: the animals, the land, the people. They are denied the opportunity many of them sought: to make contact with something of their not-so-remote past, when all people lived in harmony with the natural world, not in competition with it. They are denied the opportunity to escape from a world of artifice and manipulation, qualities without which neither the game park nor the safari circuit would exist.

To some extent we are all prisoners of our own culture; traveling to other lands gives us a chance to break out temporarily and briefly taste what it is to be not just somewhere else, but someone else. Tourists, however brief their visit, have the satisfaction of knowing that under other conditions they could have been other than they are; they discover an unknown potential by sharing in the cultural achievements of other humans.

Our longstanding fascination with animals is not so different from our fascination with other cultures and, of course, it is primarily the animals that bring tourists to East Africa. But it is more than just wildlife they seek, and the clues to the real nature of their quest lie all around. Deep in

our past, our ancestors painted on the walls of caves. They left us a vivid portrayal of man seeking and making contact with animals that goes far beyond simple depictions of the hunt, of hunters and their quarry. They also show us a powerful sense of kinship, a sense of two worlds that belong together. These worlds have somehow become wrongly and artificially separated. The ancient cave paintings show a perception of a power that is more than physical and testify to a belief that this power can be transferred from one world to the other. Neither humans nor beasts are shown as superior; both have their proper realm of potency. Our folk tales of today tell of animals acquiring human powers such as speech and abstract thought. In the days of our ancestors it was the other way around: we sought to acquire the power of other animals.

At the dawn of humankind, man and beast lived in much greater proximity. They sheltered in the same caves. In parts of East Africa, the skulls of the dead were until recently placed far in the rocky recesses of caves, as though human death were somehow mitigated through the ongoing presence of animal life. Today our concern for immortality (surely the greatest quest of all) is directed toward the stars. That is where we seek signs that we are not alone in the universe, that we are part of something infinitely greater and more enduring. Our cave-dwelling ancestors looked to the stars too, but they also looked to the animal world to find something of themselves there, seeking to find the fullness of their nature and the extent of their greatness and power. But that was before we domesticated animals and taught ourselves that we were superior. The tourist in East Africa may well be trying to reach back, searching for a lost identity and a sense, however tiny, of immortality.

The early interrelationship between man and beast, both affective and effective, mystical and practical, soon became formalized in complex systems of totem and taboo, systems that stressed the proximity of all living things, rather than their distance. The medieval European system of heraldry perpetuated the notion of a mystical bond between families of men and families of animals. And today, we have bestial national emblems and royal or sacred, protected species. Play and dance, both highly educational

activities, still relate us to the animal world, although perhaps less directly than in East Africa, where the play-*bomas* teach children how to identify an almost unlimited variety of cattle and where dances in imitation of fighting bulls may serve to explore and resolve disputes between humans. Leapfrog is still with us, as is the ancient game of snakes and ladders.

Right up to the present day the animal world has been kept at the forefront of our consciousness, as it was in the earliest times, by a body of mythology that has connected humans with beasts, deliberately blurring the lines of distinction. The Greeks, among many other peoples, suggested that gods mated with humans, resulting in creatures that were half human and half beast, and therefore semidivine.

When we look at the Middle Ages in Europe, we get a better perspective on our ongoing involvement with animal imagery, one that suggests that throughout history some human beings, at least, have seen animals as intermediaries, as vehicles to attaining a power exceeding that of ordinary mortals. Animal symbolism flourished in both the sacred and the secular worlds. While the Christian Son of God was portrayed as a lamb, the Antichrist was portrayed as the lamb's cousin, the goat. The Devil was believed to seduce both male and female while in the form of a goat rather than in human form, suggesting that in animal form he was even more powerful. Medieval court records overflow with the testimony of accused asserting that they had voluntary carnal relations with the Devil or one of his agents, who appeared in a remarkable diversity of animal forms. The conjunction of human and beast was believed to lead to a creature of supranatural rather than supernatural power, and some actively sought power in this way.

Animals were tried alongside their human companions and not infrequently executed with them. Just to keep a pet or feed a stray cat was often enough to warrant an accusation of consorting with the Devil, for the real intimacy that was feared was spiritual, rot physical. Such intimacy led to a transfer of powers that, in the Middle Ages, was thought to result in evil, since the conjuction of human and beast had never been intended by the Divine Creator. Man was reaching too far, committing a blasphemy,

just as some today feel that man is committing a blasphemy in reaching for the stars. Yet so deep-seated is this yearning for a sense of intimacy with all other living things that even today, when we would laugh at the notion of consorting with the Devil or of acquiring supranatural powers through the use of a familiar (a spirit, often in animal form), we still persist in the attempt to bridge the gap between the two worlds. The depictions of animals in children's books, comic strips, and animated films are only some of the ways we make contact, under pretense of fantasy. What did those Californians mean when they said that Disneyland was both more "real" and more "natural" other than that, for them, it united the two worlds more readily than mere observation of live animals in a game park? Disneyland gives life to the ancient fantasy of oneness, but in a way that is respectable. It makes the gap between the two worlds seem less important, if not nonexistent.

Is it really too much to suggest a connection between medieval concepts of witchcraft power and contemporary fascination with animal imagery as represented by Disneyland? What of the deeply entrenched custom of keeping pets? Consider the possibility that we all have our own familiars; it is not difficult to see that in our favored animal form we find qualities that we admire or envy or fear, that we feel to be latent within us and that, through association and proximity, we hope to control or bring to the surface. For many, the pet becomes almost an alter ego.

Everywhere we look, from the cave paintings of the remote past through the mythology of the ancients, in the witchcraft beliefs of our immediate ancestors, and even in our own contemporary customs and usages, we are surrounded by animal imagery, whose significance we dismiss only today. The tourist in East Africa can hardly avoid being affected by this pervasive imagery and may well be trying, however unconsciously, to abolish the distance and separation that modern man has created, a distance that far from ennobling us seems to diminish us. In seeking proximity to that other world or that other part of our own world, tourists may not be in search of supranatural power but are surely seeking to enlarge their own sense of being. And in those rare moments of solitude, the tourist can scarcely fail

to glimpse the full potential that comes to us all when we see ourselves as a small but essential part of a world much wider and grander than the one that we have manufactured exclusively for ourselves.

When tourists add "Africa" and "Kilimanjaro" to "animals" on their list of objectives in coming to East Africa, they seem to me to be plainly stating one objective, not three. They expect an indivisible, natural whole made up of both human and animal components. But unless they are unusually lucky this is not what tourists find on the organized safari. All that is observed is man-made: game parks devoid of the herders and hunters who used to live there as an indispensable part of the ecosystem. The movements of the game itself have been distorted by, or adapted to, the movement and behavior of tourists in their variety of vehicles. The animals, far from retaining their independence, have in every sense become as dependent as pets, for we have taken control of all that lives and moves and dies in the park. Even Kilimanjaro, seemingly majestic as ever, has lost something, for the greatness of that mountain lies not so much in its height and grandeur but in the beliefs and hopes of those who live on its slopes and in the plains stretching far into Africa on all sides. Many of those people have been moved in the name of progress (and tourism), their whole way of life has been changed, their beliefs taken from them. To know Kilimanjaro is not just to see it, but to touch it, say, through the life of an old man or woman to whom it is still sacred. And that is precisely the way to know the animals in Africa.

To know the wildlife is to float down the Semliki in a canoe with men whose harpoons are poised, waiting for the reeds that some hold between their fingers to betray the presence of a submerged hippopotamus. Then you will know that animal as you can never know it by watching it yawn in the muddy waters of a game park puddle. And as the harpooned, still submerged hippopotamus takes off, towing the canoe at the speed of a powerboat, you will come to know what it is to be the hunter, full of respect and compassion for the prey. Without the hunter the game park is just another Disneyland, another of man's fantasies. The hunter kneeling in a canoe, standing high on an anthill, or climbing a solitary tree in search of a possible kill is an essential part of the world the tourist really wants to know.

I met some tourists who specifically came to recapture something of what they see as their lost identity, man the hunter. Many of them had previously been on big game hunts, but having had their share of killing had been left unsatisfied. The hunter of our past was strangely nonviolent; he killed with no animosity, no sense of superiority, only because it was necessary to survive. Not far away, across the border of Uganda and into Zaïre, live the Mbuti, a people who, with a pre–Stone Age technology, still survive by hunting and gathering. They tell a story of how God created all living things—animal, vegetable, and mineral—endowing them with different degrees of life force but making them all immortal. Then one day, one of these living creatures, man, killed an antelope. And although he and his family consumed the animal entirely, making use of all its parts so that none went to waste, God cursed the day and ordained that from then on all animals, including humans, would die. Since that day, the Mbuti say, they have had to kill to survive, but they kill only the minimum they need for each day, saving nothing for the morrow, in the hope that if only they can learn again how to survive without killing their fellow creatures, they may regain their immortality.

A thousand miles away the Bushmen, whose ancestors may well have come from the plains below Kilimanjaro, tell an almost identical story. The experience of human beings living as an integral part of a connected, natural world is what pilgrims/tourists mainly seek when they come to Africa. The animals are the means by which the culture-bound pilgrim can grow and expand, sensing a unity with all other living things and finding a greater potential through another source of power. And if our history tells us anything, if there is anything to be found in the art and literature of all ages, it is that through contact with the animal world we can touch the mystery of life itself and for a fragile moment know what it is to be semidivine, immortal.

Colin Turnbull, formerly associate curator of African ethnology at the American Museum of Natural History, is visiting professor of anthropology at George Washington University.

In fine pewter, painted by hand

The Songbird Miniatures

by Anthony J. Rudisill

Enchanting, jewel-like beauty in sculptured form . . .

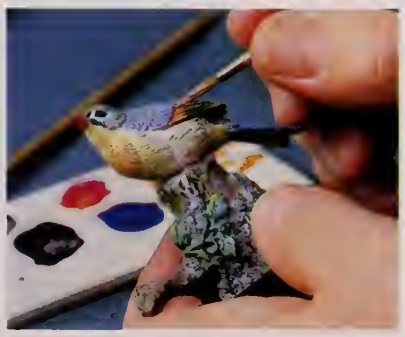
Twelve songbird miniatures, each one an original work of art in hand-painted pewter . . .

A superb display, a focus for conversation and admiration in the most elegant room

A darting flash of brilliant color. A lilting melody as pure and clear as fresh spring water. The *songbird.* Admired and cherished for its grace and beauty. Painted and sculpted throughout the ages in works of art collectors watch for with special keenness.

And now created in one of the most fascinating, most beautiful forms of all. Combining the rich color of painting . . . the three-dimensional realism of sculpture . . . and the unique charm and appeal of the traditional *fine art miniature.*

'The Songbird Miniatures' collection is the creation of the noted wildlife artist, Anthony J. Rudisill, whose work is frequently commissioned by the National Wildlife Federation. It is his very *first* work for the medium of pewter — selected for its unique ability to capture fine detail. And it is the *first* such collection issued by The Franklin Mint.



Rich, hand-painted colors

The collection comprises twelve beautiful songbirds from around the world . . . each sculptured in intricate detail and with a powerful sense of realism.

To ensure that the artist's designs are reflected with complete faithfulness, each pewter miniature will be cast by master craftsmen in Malaysia . . . specially chased and finished . . . meticulously *painted by hand* in colors having all the richness and subtlety of nature . . . and coated with a protective finish to permanently preserve the sculpture's true-to-life appearance.

A limited edition

'The Songbird Miniatures' will be issued in a limited edition, available exclusively from The Franklin Mint and only for one year, until May 1982. After all valid subscriptions have been fulfilled, the molds will be broken. Thus the total number of collections issued will be permanently limited to the exact number of applications received during the subscription period.

Each songbird is sculptured exactly one-half life size in a natural setting, and hand-painted in Nature's own colors

Advance subscription deadline: May 31, 1981

You are among the first to have the opportunity of acquiring 'The Songbird Miniatures'. But please note that the advance subscription application at right must be postmarked by May 31, 1981. As a subscriber you will be able to build your collection systematically, receiving one songbird miniature every other month. And the issue price for each sculpture — just $45, remarkable indeed for an original work of this quality — will be billed to you in two convenient monthly installments of $22.50 each.

But please note that the application at right should be signed and mailed to The Franklin Mint, Franklin Center, Pennsylvania 19091, by May 31st.

© 1981 FM

ADVANCE SUBSCRIPTION APPLICATION

Valid only if postmarked by May 31, 1981.
Limit: One collection per subscriber.

The Franklin Mint
Franklin Center, Pennsylvania 19091

Please enter my subscription for 'The Songbird Miniatures', a collection of twelve miniature sculptures cast in fine pewter and hand-painted. The miniatures will be sent to me at the rate of one every other month.

I understand that I need send no money now. I will be billed for each miniature in two equal monthly installments of $22.50*, the first installment being due in advance of shipment. I may return any figure within thirty days for replacement or full refund.

**Plus my state sales tax and $1. per shipment for postage and handling*

Life Returns to Mount St. Helens

One year after a major eruption turned much of the mountain into an apparent grave, the slopes show abundant signs of resurrection

by Roger del Moral

Picking my way across a dry and barren mudflow 5,000 feet up on the slopes of Mount St. Helens last September, only four months after the eruption that devastated the mountain and far from any visible vegetation, I discovered an isolated, yet active, ant nest. These ants, probably *Formica subnuda,* were at the top of a food chain whose lower levels, hidden in the mudflow, were unknown. Decomposing organisms and living plants may have formed the base of the chain, but without disturbing the nest, I could not determine whether soil animals or fungi were involved. Despite my curiosity, I decided that my ignorance was less important than the existence of this microcosmic ecosystem in a veritable desert. The ants were adding nutrients to the mud and hastening the reestablishment of less ad hoc food chains. After watching the activities of these tiny survivors for a while, I continued up the slope, searching for signs of life among the ruins of what was once the most perfect of the Cascade volcanoes.

As Mount St. Helens marks the first anniversary of its May 18, 1980, eruption, it has already been exposed to more hours of scientific scrutiny than most volcanoes are ever subjected to. Logistical and technical problems plagued efforts to study earlier eruptions of other North American volcanoes. Mount Katmai in Alaska, for example, erupted in 1912, but ecologist R. F. Griggs (to whom scientists owe a major debt for his pioneering botanical and geologic studies of that volcano) was unable to approach the mountain until 1916. By contrast, the proximity of Mount St. Helens to scientific centers provides a rare opportunity to apply advanced methods in comprehensive, long-term studies of how ecosystems recover after a major volcanic eruption.

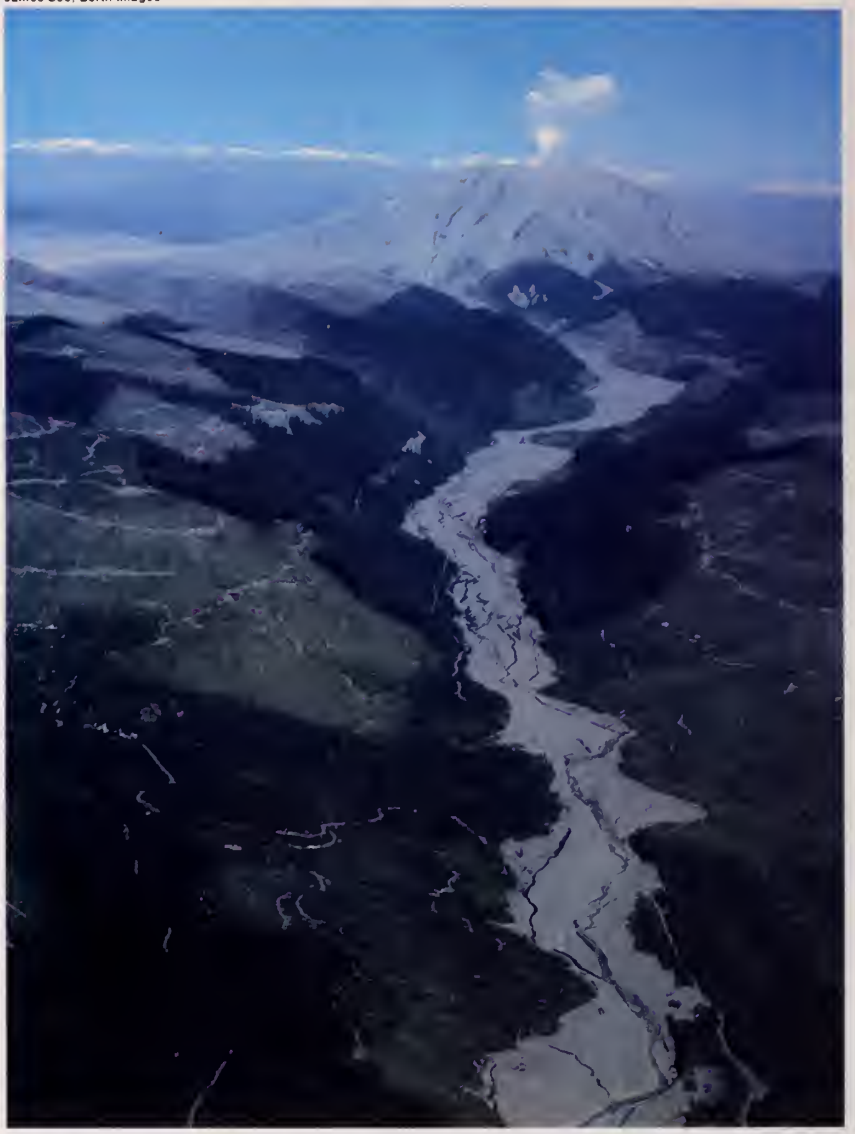
As an ecologist interested in competition and succession in stressful environments, I found myself among the hundreds of scientists drawn to the mountain by the opportunity to document in detail the recovery process and by the exciting chance to test ecological, evolutionary, and biogeographical hypotheses. Biologists observing events as they unfold on Mount St. Helens are asking many questions: Which species first colonize the various completely destroyed habitats? Are succession processes on totally denuded sites fundamentally different from processes on sites with a residual biota? Does repeated extinction and recolonization result in populations that are genetically distinct from populations of the same species in stable habitats? Might communities whose species occur in proportions different from the regional norm be produced?

Ray Atkeson

Above: Residents of Portland, Oregon, had a spectacular view of the July 22, 1980, eruption of Mount St. Helens, one of several sizable blasts that followed the major eruption of May 18. The mountain's proximity to urban centers has been a boon to scientists. Right: Two months after the May 18 eruption, a parsley fern was found growing in a protected area along a creek on the slope of the mountain. The fern, which survived a small mudflow, is growing out of a mud-covered crevice.

My first field experience on the volcano after the eruption was on a reconnaissance trip last July with Jerry Franklin of the U.S. Forest Service and several other biologists. While we were awed by the magnitude of the destruction, I was impressed even then by the early evidence of biological recovery. Since that time, I have made several research trips into various parts of the volcano's "red zone" (the Forest Service's designation for the potentially most dangerous land, to which access is closely controlled). I have also spoken with many other scientists investigating resurrection on the mountain. The emerging picture is one of diversity—diversity of impact and, consequently, of the conditions to which organisms must adapt. Al-

Roger del Moral



titude and season influenced the nature and extent of the damage suffered by different parts of the mountain. In May, much of the landscape was still covered with snow. By contrast, when I visited the volcano late in the summer of 1980 after a minor eruption, I found that hot-gas emissions had scorched exposed plants. These withered bits of straw provided an inkling of what might happen if a big eruption occurred when there was no snowpack to cushion the blow.

The May 18 eruption, like subsequent smaller eruptions, was a series of events, each producing different conditions. In some places, biotic recovery has begun with survivors; in others, colonizers from outside the impacted zone are required. Many ecosystems won't return to anything resembling their preeruption state for years. But almost all affected ecosystems are showing resilience, and the message is clear: while it took a beating, life was never obliterated from Mount St. Helens.

The eruption, which followed two months of relatively minor volcanic activity, unexpectedly concentrated its force on the land to the north. Although geologists had anticipated a major eruption and the magnitude of the blast was not unprecedented, no one was prepared for the degree of devastation spawned by the unusual lateral direction of the eruption. More than a cubic mile of ash was injected into the atmosphere, eventually coating hundreds of square miles of forest and agricultural land. Millions of insects were knocked dead from the sky. Heat scorched trees up to sixteen miles north of the crater, and the blast blew down trees in an arc of 160 degrees, extending more than ten miles from the crater. In most areas within a six-mile radius of the crater all life was destroyed. Large, rapid mudflows, confined to the lower elevations of several of the mountain's major stream systems, crested over twenty-five feet and buried the flood plains of the Muddy River to the east and both forks of the Toutle River to the west. A flow of hot debris then swept all life from the northern flank of the mountain and the upper Toutle Valley, creating an eerie moonscape. (Unlike the sterile surface of the moon, however, the debris is rich in organic residuals.) Melting glaciers and snowfields triggered smaller mudflows on the upper slopes. For example, on the southeast flank of the mountain, the melting of Shoestring Glacier caused a mudflow along Pine Creek that covered vegetation on the edges of the creek while removing it from the creek bed. In total, the eruption of Mount St. Helens had a profound impact on a region of about 160 square miles.

James Lee, Earth Images

The number of animals killed as a direct result of the explosion was high. Subterranean animals, such as pocket gophers, appear to have survived in many places even within the blast zone, but mammals and birds living above ground had no protection from the blast. The Washington Department of Game estimates that among the more prominent casualties were 5,200 elk, 6,000 black-tailed deer, 200 black bears, 11,000 hares, 15 mountain lions, 300 bobcats, 27,000 grouse, and 1,400 coyotes; the agency has estimated heavy additional losses due to ashfall. The eruption also severely damaged twenty-six lakes and killed some eleven million fish, including trout and young salmon.

Animals outside the blasted areas must contend with altered habitats and reduced quantities and quality of food. In the blowdown zone, elk and deer are now common near water and where fresh forage has emerged from the ash. These survivors may have to forage more widely, but their reduced numbers will ease competition stresses. Zoologists expect the populations of vertebrates to build up as the vegetation recovers, and they are hoping to determine how much the vertebrate pioneers may change their behavior with respect to habitat and resource use as their numbers increase. Significant changes in behavior would constitute evidence for interspecific competition, normally difficult to observe in nature.

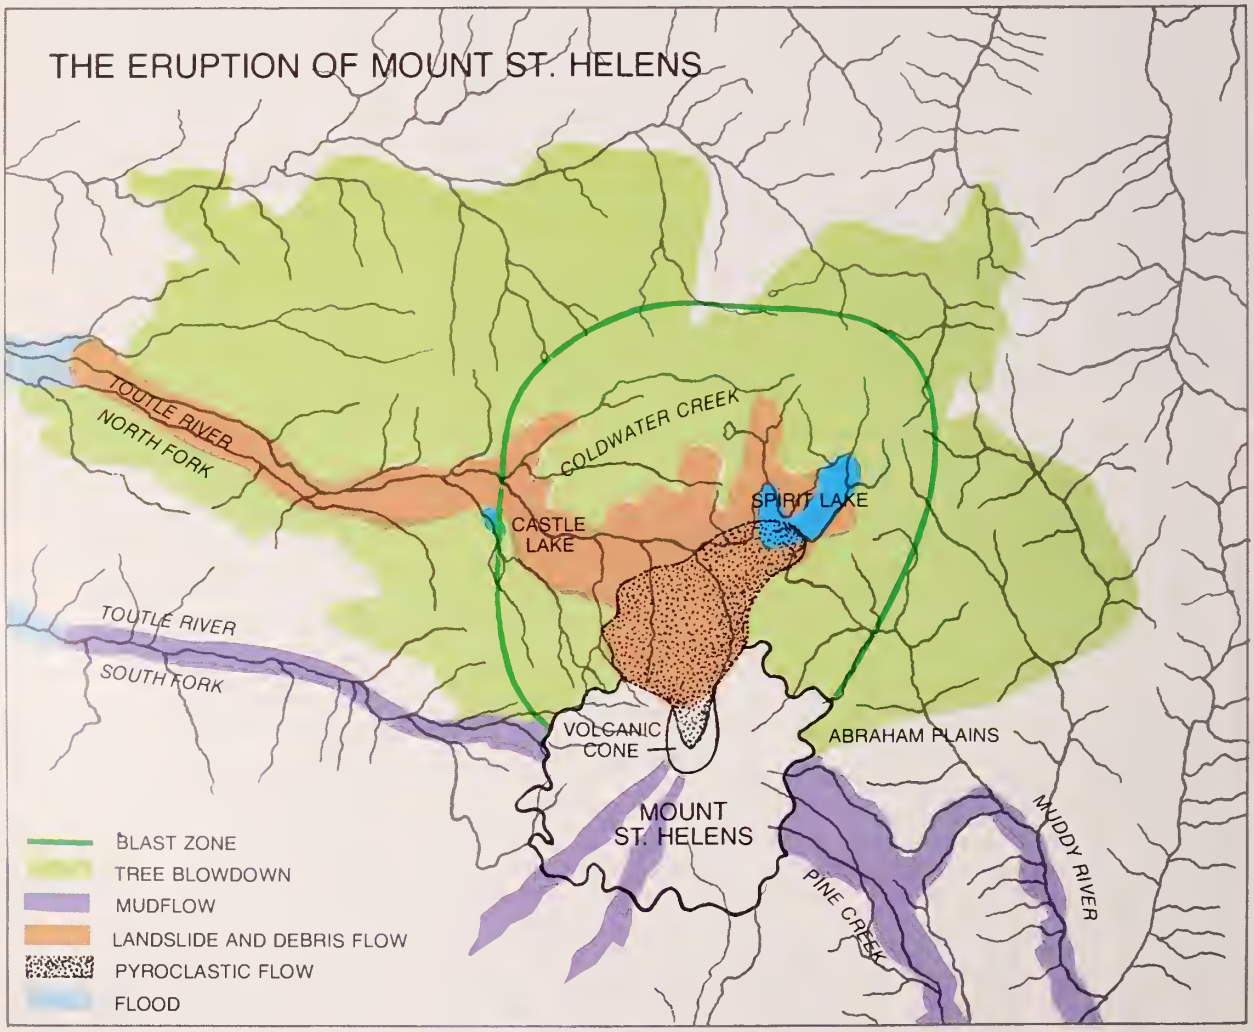
Ralph Perry

Far left: Twelve miles or so west of Mount St. Helens (visible in the distance), clear-cut and forested areas along the North Fork of the Toutle River escaped direct effects of the eruption. Large, rapid mudflows, however, buried the river's flood plain. Left: Closer to the volcano, trees were blown down and a hot debris flow, placed on top of the mudflow, swept all life from the upper Toutle Valley.

Larger vertebrates may form a crucial link in the process of vegetation recolonization. Where heavy ash or mudflows dried to form a hard, uniform crust, there are few cracks to shelter germinating seeds. But large animals wandering in search of food or water make tracks that trap seeds and provide microsites suitably mitigated for germination and growth.

Insects suffered incalculable tolls, primarily from the ash effects of the May 18 eruption and from sizable blasts that occurred on May 25 and June 12. Abrasion of the exoskeleton and ingestion of ash during preening were major causes of death. Studies of agricultural areas in central Washington have revealed that although honeybees and other beneficial insects suffered greatly, most insect populations recovered quickly. Nearer Mount St. Helens, where higher altitudes mean a later spring, fewer insects were exposed at the time of the eruption. In the blowdown area, many species have been encountered, but except near water, their numbers are reduced. I noted that seed set in lupines, which are dependent on insects for outcrossing (the production of offspring from individuals of the same species but different strains), was poor even where the vegetation received little damage. I believe this poor seed production was a result of the relative paucity of pollinating insects.

Insect colonists will come from pools of insects outside the blast zone, and new insect communities will eventually develop. Will these communities be similar in species number and composition to communities in similar but unaffected habitats? Daniel Simberloff's experiments during the 1960s, in which all insects were removed from a series of very small Florida keys, indicate that such communities will soon return to the same number of species but that the composition, largely a matter of chance, will be quite different. In the Mount St. Helens blast zone, the habitat is larger than in the island experiments and there is no significant barrier to migration. Will this alter the results? Will novel, stable assemblages of insects be formed?



Food limitations present surviving insects and early immigrants with unique challenges. Species with the most generalized requirements are predicted to be successful, and some early observations in the blowdown area support the idea that survival requires adaptability. In the weeks after the big eruption, when ash was ubiquitous and aphids were rare, Jerry Franklin and I observed a ladybug, normally an aphid predator, feeding directly on the sap of a bracken fern (*Pteridium aquilinum*) that had emerged from the ash. Such short-circuited food chains should return to normal as the vegetation, on which aphids and other herbivores depend, recovers.

Because insects have short generation times and are often early colonizers, entomologists are likely to observe microevolutionary events, which involve shifts in gene frequency rather than speciation. For example, where biotic recovery requires immigration, the first individuals of a species to invade an area are, not surprisingly, usually the best able to disperse. Reduced competition and the absence of predators in their new environment may permit a "founder effect" to occur, that is, the genetic differences between founding individuals and the average members of the donor population become fixed. Such differences will probably be minor, but if they occur repeatedly in many species, biogeographical processes that are known to operate between islands will have been shown to be significant for evolutionary processes in terrestrial situations as well.

The effects of the eruption on vegetation in various zones are also under study. In forests within a few miles of the mountain, the initial ash deposits fell wet because of eruption-induced thunderstorms and covered the trees and ground with a thick goo, which soon dried to form an impervious, cementlike layer. Ash on vegetation interrupts gas exchange and curtails photosynthesis. Jini Seymour of the University of Washington measured temperature in ash-coated silver firs (*Abies amabilis*) and found them to be more than 30°F warmer than adjacent leaves from which the ash had been removed. Fortunately, since heavy ash fell prior to bud burst in higher elevations, much ash-free new growth is now present in most of the surrounding forest. As ash-covered leaves are washed clean by precipitation or replaced by new growth, conifer productivity should return to normal. Some species, such as red cedar (*Thuja plicata*), retain ash more tenaciously than others, such as Douglas fir (*Pseudotsuga menziesii*), but

Eyewitness accounts, photographs, and instrument records have been used to piece together the initial sequence of the May 18, 1980, eruption of Mount St. Helens, the youngest and most active Cascade volcano. A huge bulge formed rapidly, high on the north face of the mountain's volcanic cone, in the weeks prior to May 18. Then, at 8:32 A.M. on that day, an earthquake struck the mountain, triggering an avalanche on the north face that is now thought to be the largest ever witnessed by humans. Superheated groundwater close to the magma flashed into steam, resulting in a lateral explosion that pulverized rock and trees and sent a hurricane-force, hot-gas-propelled bolt of ash off the north face and across the Toutle River Valley to the north and west. Temperatures in this inferno were estimated to exceed 900° F. Comparable to a 400 megaton nuclear blast, the explosion blew down trees in a 160° arc up to fourteen miles north of the crater and totally devastated a somewhat smaller "blast zone." Seconds later, overlying rocks were incorporated into a high-velocity debris flow, driven by rapidly melting glacial ice. On the western flank of the mountain, this chocolate-colored mass swept down the upper Toutle River Valley, eventually forming a mudflow that swept the entire drainage area. To the north, a lobe of this hot debris flow crashed into Spirit Lake while another swept over 500-foot-high Coldwater Ridge, removing all life in its path. As the summit of the mountain collapsed, two vertical columns of ash-laden gas and steam were injected more than 65,000 feet into the air. This ash was eventually deposited, in layers up to five inches thick, over 49 percent of Washington State and beyond. Close to the mountain, ash deposits were less thick, but they fell wet, forming a sticky goo on all surfaces. The plume of blasted ash also removed much of the remaining summit and lowered the peak from 9,677 feet to about 8,400 feet. As a consequence, the feeding zone of all glaciers has disappeared. Shortly after these events and continuing throughout the next day, an indeterminate number of pyroclastic flows, or nuées ardentes *(hot, gas-charged avalanches of fluidized rock fragments), were ejected from the crater, so that much of the upper debris flow was covered with more than seventy feet of finely powdered ash and pumice.*

The volcano remains active, with frequent small, harmonic tremors and occasional bursts of steam and ash. Sizable eruptions, with their attendant small pyroclastic and pumice flows, occurred on May 25, June 12, July 22, August 7, October 17 and 18, and December 27 of last year. Future eruptions are expected, but most geologists believe that another large eruption is not likely.

whether various species of forest trees will show important differences in mortality or productivity is not yet clear.

At higher elevations, snow protected the plants beneath the canopy of forest trees from direct ash deposits, but impacts still accrued in this understory vegetation. Many plant species already flattened by snow were trapped by heavy ash. Erosion and rain may eventually remove sufficient ash to free such plants, but the damage may have been too severe or too much of the growing season may have passed for them to survive. Mosses and lichens, which form low mats, are the most severely damaged. Other species, such as the erect-growing huckleberries (*Vaccinium* spp.), were able to emerge from the ash layer as the snow melted. These plants grew well during 1980, probably because there was less competition from other plants and because the high insect mortality reduced grazing pressure. Many of these emergents have sent roots into the nutrient-rich ash and may thus benefit directly from improved nutrition.

Jim MacMahon of Utah State University has shown that pocket gophers are major agents of ash-layer disruption. These little burrowing rodents improve soil aeration and water infiltration. As a consequence, minerals from ash are more rapidly incorporated into the soil, where they can be used by plants. Silviculturists normally view pocket gophers as unmitigated pests because they eat young conifers, but for the next few years, gophers may prove valuable allies in the reestablishment of tree seedlings in clear-cuts and blowdown areas.

For most plant species, recovery in heavily ashed areas will be rapid. Young Douglas firs, silver firs, and noble firs (*Abies procera*) may suffer heavy mortality, and species of lichens, mosses, and other low-growing plants will be disproportionately rare for many years, but overall forest productivity should soon return to pre-eruption levels. When nutrients from the ash, such as phosphorus and potassium, are added to the soil, they may actually generate a pulse of enhanced productivity. Understanding the differential effects of Mount St. Helens' ash deposits on vegetation will improve the ability of ecologists to read the history encoded in tree rings, pollen records, and soil profiles in other volcano-dominated ecosystems.

Less apt to survive than trees that were primarily subjected to ash deposits are the scorched conifers found in a narrow but expanding band between green timber and standing dead trees. Many trees in this border zone, such as western hemlock (*Tsuga heterophylla*), Douglas fir, and noble fir, survived the initial surge of heat and gas from the main eruption but were weakened by it and also received heavy ash deposits. During the dry summer, many trees gradually succumbed from internal heat or other factors. Fortunately, young saplings beneath many of these trees escaped virtually unscathed by virtue of the snowpack present during the eruption. Thus, the next conifer generation is already well established and should experience a burst of growth now that the saplings are released from competition with their parents.

Still closer to the volcano, where stands of large trees did not survive the first blast, stark contrasts appear between areas that had been clear-cut shortly before the eruption and areas that had been covered with forest. In most parts of the blowdown area, snow again offered some protection to ground-layer vegetation, and terrain closest to the mountain received less ash than more distant areas directly in the path of fallout. In the clear-cut areas, regeneration of herbaceous vegetation began shortly after the eruption. Species that commonly grow on recent clear-cuts, such as fireweed (*Epilobium angustifolium*), pearly everlasting (*Anaphalis margaritacea*), and bracken fern, have ecological characteristics distinct from those of forest understories. They grow fast, produce many easily dispersed seeds, and are able to colonize newly disturbed sites rapidly, tolerating high light, high temperatures, and drought.

In contrast, areas in the blowdown region that were covered by deep forest at the time of the eruption lacked herbaceous vegetation as snows returned in the winter of 1980. The forest understory normally consists of herbs and shrub species adapted to cool, moist, dark conditions. These grow slowly; produce few, poorly dispersed seeds; and are intolerant of high-light or high-temperature conditions. Any such understory plants that survived the adverse impact of the blast and ash layers were thus confronted with an inimical environment.

Recovery in these blowdown areas will require invasion by aggressive species from the surrounding clear-cuts. As succession proceeds, conditions will gradually alter in favor of species adapted to the forest. A major prediction to be tested during the 1981 growing season is that within the blowdown area, pioneer species from clear-cuts will make up the bulk of new growth in the once forested parts. However, since the flattened trees create microsites favorable to the survival and regeneration of some understory vegetation, the next forest generation will be fostered by the slowly decomposing remains of dead trees.

The potential juxtaposition of plants having markedly different ecological strategies offers opportunities to test some ecological theories. Prevailing opinion would predict, for example, that in open microsites, pioneer species should outcompete the forest species, whereas in protected sites, the reverse should happen. As conditions improve, overall dominance should rest with forest species.

The region of tree blowdown and its surrounding ring of moribund trees presents the U.S. Forest Service with difficult management options. Standing dead and downed trees ameliorate the microclimate of the substrate, retard erosion, and foster natural succession. Trees blown into stream channels reduce erosion and siltation and promote the recovery of streamside vegetation and fauna. Furthermore, there is a widespread desire to preserve much of this region for interpretive, recreational, and scientific purposes. The Forest Service, which manages most of the affected land, must reconcile these factors with the value of downed timber and the danger of fire or of beetle infestations in Douglas fir, starting in moribund vegetation and moving into healthy, economically valuable forests. Salvage removal of downed timber is beginning, although not in areas designated for detailed study by the Forest Service Special Planning Team.

Flood plains are intrinsically unstable habitats, and those in the area affected by the May 18 eruption will recover more slowly than either the ash or blowdown zones. The mudflows, which swept the lower thirty-two miles of the North Fork of the Toutle River, fifteen miles of the Muddy River, and many smaller streams, removed most of the vegetation in their path before settling into unstable masses. Erosion rates will be high, and successful seed invasion will be limited for many years. Last July I observed cottonwood

Douglas C. Anderson

In many places, trees that withstood the blast were scorched by heat and noxious gases and covered with ash. Where this occurred, the mountain shows a line between brown, dead trees and green, living ones.

(*Populus trichocarpa*) seedlings colonizing the lower North Fork of the Toutle. Because they float through the air, cottonwood seeds were among the few seeds available shortly after the May eruption. Unfortunately, subsequent erosion from minor summer rains washed these seedlings away. Bob Zasoski of the University of Washington has estimated that more than ten years will pass before the first trees are established on these mudflows and more than a century before a more or less normal forest can develop.

While mudflows devastated the lower river valleys, a huge debris flow —a turbulent, water-driven, hot mass of rocks, boulders, and uprooted trees —ravaged the upper valley of the Toutle's North Fork. A few plants miraculously survived the vast jumble, and an occasional fireweed or bracken fern rhizome sprouted, but recovery on this debris flow will depend primarily on seeds invading from less damaged areas.

Comparisons between the broad debris flow on the North Fork of the Toutle River and the much narrower mudflow, close to intact vegetation, on the South Fork will provide a test of the hypothesis that the recovery rate on a site from which vegetation has been totally obliterated depends on the proximity to a pool of colonists. According to this hypothesis, recovery should proceed much more rapidly on the South Fork than on the North Fork.

Experimental manipulations of plots established on the debris flows during the next several years may also help answer some general questions about succession. Is there a definitive sequence to the recovery pattern or do chance and local seed availability dominate the process? Are the activities of specific colonizing plant species required to facilitate the subsequent success of other species? One way to test such hypotheses is by determining whether, after a number of years, plots

John Marshall

from which the first colonists are periodically removed differ from control plots. Another question of interest is whether succession tends to converge toward a single community type or whether initial site differences persist indefinitely. This question may be answered by comparing the initial degree of vegetation heterogeneity with that found five or ten years later. Significantly reduced variety would imply that convergence is indeed occurring.

Several slower and less publicized mudflows were driven by glaciers melting on the east, south, and west slopes of Mount St. Helens. Last September, I visited the upper portion of the six-mile-long Pine Creek mudflow, which was propelled by the now nearly defunct Shoestring Glacier on the southeast flank of the volcano. Although the preeruption vegetation in this location is not known, the area still reveals interesting aspects of vegetation recovery. The heat and toxic fumes of the main eruption killed the sparse lodgepole pine (*Pinus contorta*) and subalpine fir (*Abies lasiocarpa*) scattered on the high ridges above Pine Creek. The subsequent mudflow destroyed creek vegetation but it merely buried the snow-covered dormant ground cover of the ridge. Initially there was no vegetation on the mudflow, which varied in thickness from a few inches near the treeline to more than five feet at its upper end. The Cascade aster (*Aster ledophyllus*) was the first plant to emerge through this mud. Other herbs, including the broad lupine (*Lupinus latifolius*) and Newberry's knotweed (*Polygonum newberryi*), did not emerge until light rains created small erosion channels along which these plants were confined. Where mud was more than about a food deep, no vegetation emerged in 1980.

Since mud seals the soil and can limit oxygen exchange, buried vegetation may be suppressed through the inhibition of root respiration. An alternative mechanism, however, may operate on mudflows and in areas of heavy ash deposition. Both mud and ash insulate the soil and create a light barrier, two characteristics of a snowpack. Many plant species here and elsewhere may be fooled into "thinking" that winter continues. If this is so, as the 1980/81 winter snowpack melts and further erosion cleanses the mountain, surviving vegetation will emerge, having missed a growing season but otherwise unscathed.

North of Pine Creek lies Abraham Plains, a site that supported only limited vegetation prior to the May 1980 eruption. After the initial eruption, pyroclastic and hot-ash flows melted snowfields on the mountain's northeastern flank. The resultant mudflows covered or removed all vegetation on these plains. Revegetation in this area, unlike Pine Creek, will thus depend entirely on seed immigration.

The differences between recovery due completely to immigration and that abetted by residual vegetation will be documented in permanently marked plots at Abraham Plains and Pine Creek. Questions about succession under stressful conditions will be addressed. Do survivors and immigrants belong to the same species? Or, as in the case of Abraham Plains, is the habitat so severe that pioneers are the only species capable of survival? Are differences in species composition due to dispersal failures or simply to the absent species' inability to grow in unaltered mudflow material? Answers to such questions can be applied to the future reclamation of derelict

Soon after the eruption, herbaceous vegetation began returning to recent clear-cuts within the blast zone. The pink flowers of fireweed, a colonizing species of disturbed areas, were a common sight.

James A. MacMahon

In what was once a large meadow covered with huckleberry bushes, a lone spotted frog, right, rests next to a dying bush. To support this amphibian, the meadow must still have some permanent water source.

Mammals, birds, and insects have left records of their wanderings in the ash and mud, below. Where the crust is hard, the tracks of large animals provide traps for seeds and suitable sites for germination.

John Marshall

lands in volcanic regions of the Pacific Northwest.

Further insight into recovery mechanisms will come from observations of revegetation in sites on the periphery of the directed blast. The ridges and glacial valleys in these areas escaped the debris flow and pyroclastic activity. On ridges above the South Fork of the Toutle River, for example, the few lodgepole pines at timberline were killed by the scorching blast, but the lush herbaceous vegetation that normally dominates these ridges, including the yellow penstemon (*Penstemon confertus*) and the broadleaf lupine, returned with no apparent ill effects. On the other hand, the glacial valleys below the ridges, scorched by the directed blast or scoured by mudflows resulting from melting glaciers, lost most of their vegetation. Normally, these valleys support plants different from those on the more exposed ridges, but ridge vegetation is now the most likely source of seeds for the newly exposed terrain. Mountain glaciers such as the ones that formed these valleys ordinarily retreat slowly enough for valley vegetation to keep pace. When Mount St. Helens erupted, however, the rapid melting of the glaciers not only exposed large areas for the first time in more than a century but also washed away most vegetation below the glacier. Thus, in the absence of species specifically adapted to the valleys, ridge species may expand their habitat and create novel assemblages in the valleys.

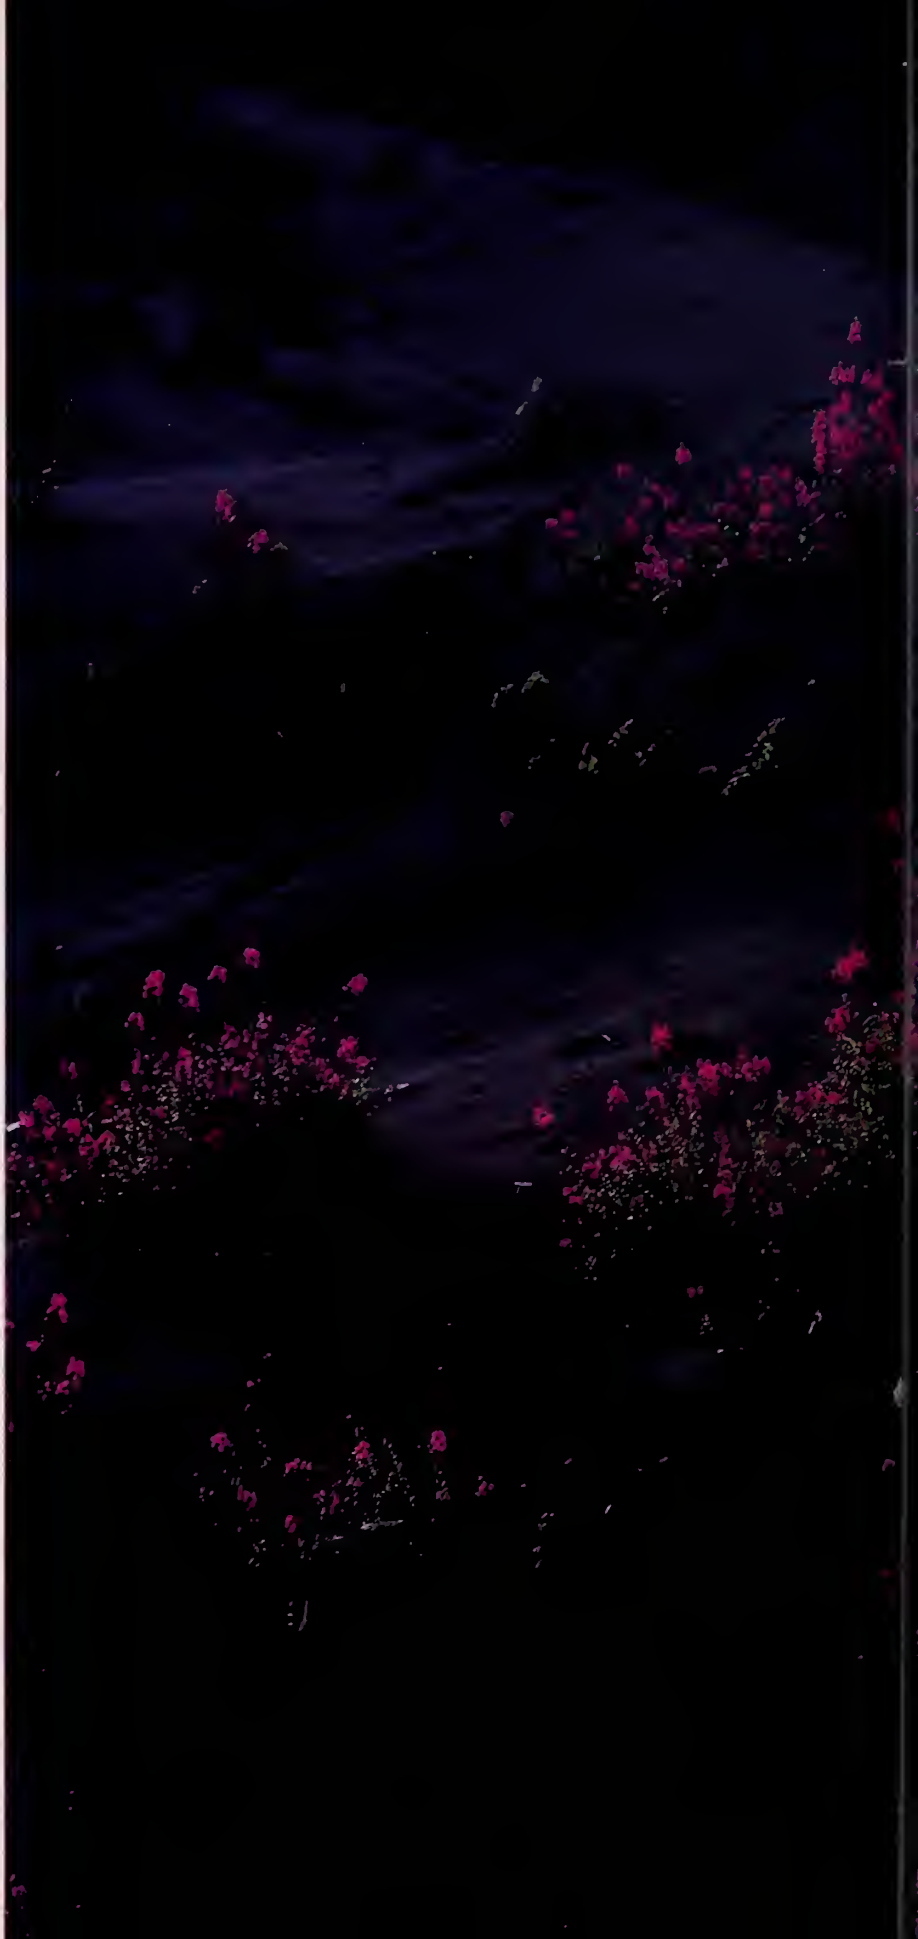
Mount St. Helens is so young and its environment so harsh that even under normal conditions only the more generalized and stress-tolerant plants can survive. All plants common to the upper slopes display adaptation to unstable or chronically disturbed environments: deep taproots, buried growing points, large storage reserves, and good dispersal mechanisms. Therefore, although ridge-dwelling plants may under normal circumstances be competitively inferior to valley dwellers, they may be physiologically capable of surviving in the valleys. I plan to monitor the development of the upper glacier valley vegetation to see whether plant communities composed of ridge species do develop. Their existence in the valleys would be strong, although indirect, evidence for the importance of competition in stressful environments.

Of all the regions on the mountain, the most severely affected was the blast zone immediately north of the crater, including Spirit Lake. Every type of volcanic behavior displayed by the mountain has assailed this terrain. All life was seemingly obliterated. Trees were pulverized and soil vaporized. Yet, even here, life is returning. Forest recovery will be slow, but it will happen. Soil development will require the establishment of mushrooms, lichens, and pioneering herbs. Seed and spore sources are scarce but a few pockets of vegetation remain. A protected ridge beyond Abraham Plains, on the eastern edge of this area, for example, supports some silver firs and a few areas of herbaceous vegetation.

Higher terrestrial life may be scarce in the blast zone but dead organic matter is abundant, and such a resource is never unexploited for long. Here, where many humans died, where entire ecosystems ceased to exist in a matter of seconds, Dave Hosford of Central Washington State College has found a mushroom, *Autracobia melaloma,* growing from the ash, slowly decomposing organic matter found there, and beginning a terrestrial succession.

Most of the biological action in the blast zone, however, is taking place in lakes. Spirit Lake, once a pristine and clear body of water and now as appealing as a sewage lagoon, teems with microscopic life. Bob Wissmar of the University of Washington, who is conducting a systematic survey of the affected lakes, has pointed out that the water in Spirit Lake was totally removed by the force of the debris flow and replaced by a hot, muddy slurry of ash and debris. Thousands of trees, blown off the mountain and washed into the lake, have provided the basis of a new aquatic food chain on the clogged water surface. As the water cooled, blue-green algae and bacteria were the first active organisms, but decomposing anaerobic bacteria and protozoans now dominate the biota. The slowly dissolving organic matter has reduced the oxygen content of the lake and continues to release prodigious quantities of sulfur dioxide, the smell of which permeates the pyroclastic zone.

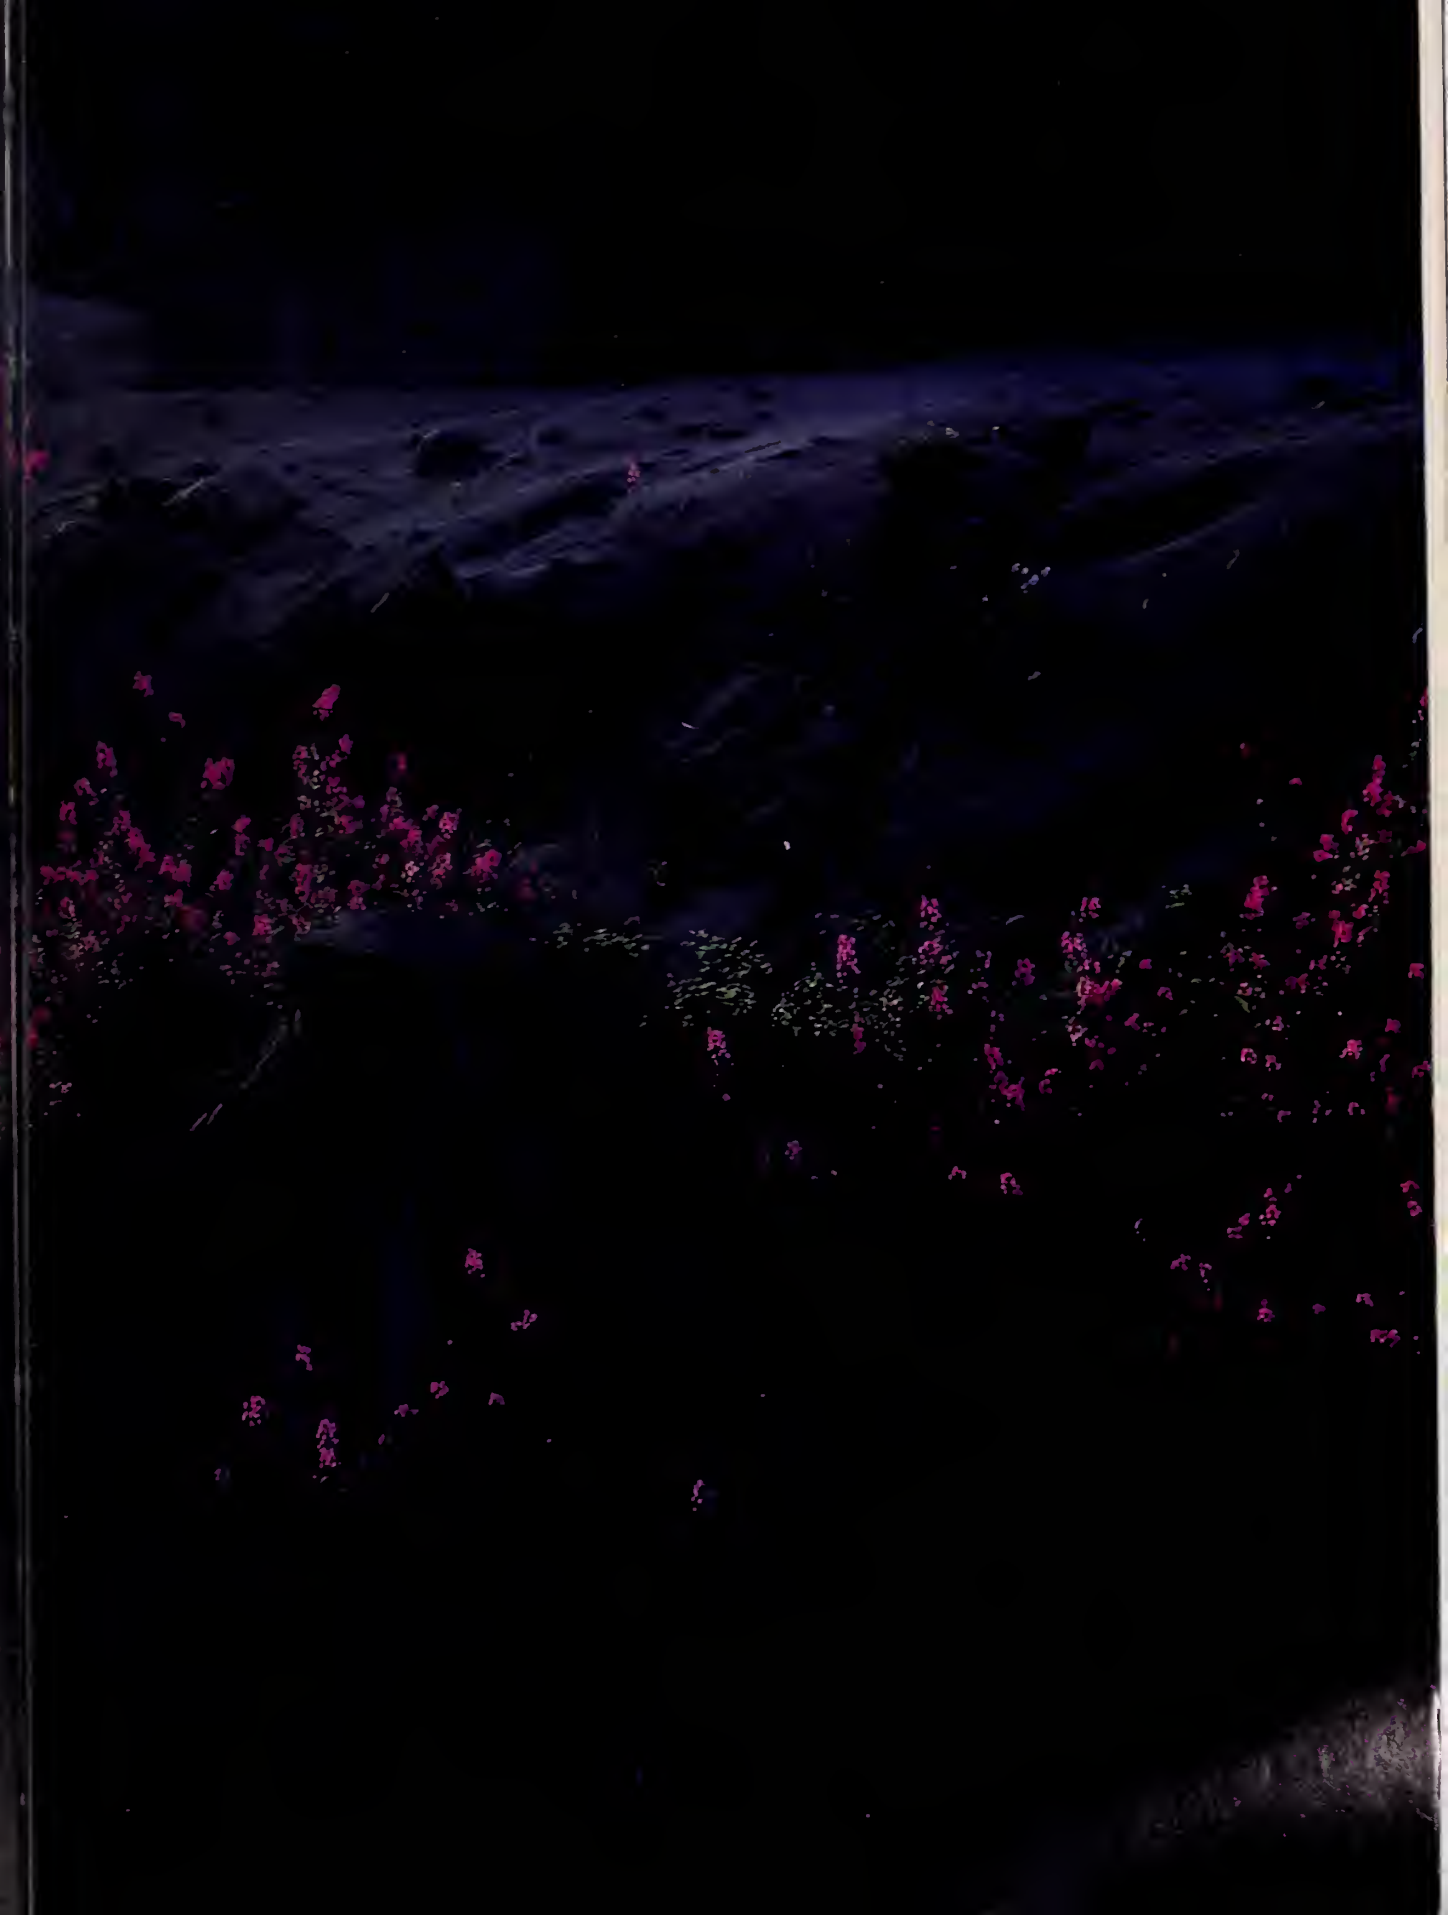
Many years will pass before Spirit Lake and other profoundly altered lakes return to a semblance of their preeruptive state. Recovery will be faster in smaller, higher lakes, which were more thoroughly protected by the snowpack. Higher lakes not hit by debris flows or mudflows were primarily affected by ash fallout and received only limited amounts of organic matter.



Ephemeral lakes, laden with organic debris and silt, pockmark the debris flow that settled into the North Fork of the Toutle River. These lakes were quite warm throughout last summer, and decomposition in them was rampant. A witch's brew of phenolic acids and tannins, smelling strongly of creosote and turpentine, is still draining from them. Tracks of elk, deer, and coyote are frequently encountered on the debris flow where little food is evident, suggesting that the animals may well be in search of water. Unfortunately, the quality of the water in ephemeral and permanent lakes is suspect. On one occasion, I found a

dead deer mouse, apparently poisoned by the tannin-blackened water in Castle Lake, which formed when the May eruption dammed Castle Creek.

As I write, the winter rains cleanse the forest of ash, and snow falls on the mountain slopes, restoring to Mount St. Helens a pristine appearance. The volcano will undoubtedly rumble for several years, however, and minor damage is likely to continue, particularly on the north slope. In such areas, the biological recovery clock may restart several times, providing future opportunities to observe several stages of succession simultaneously.

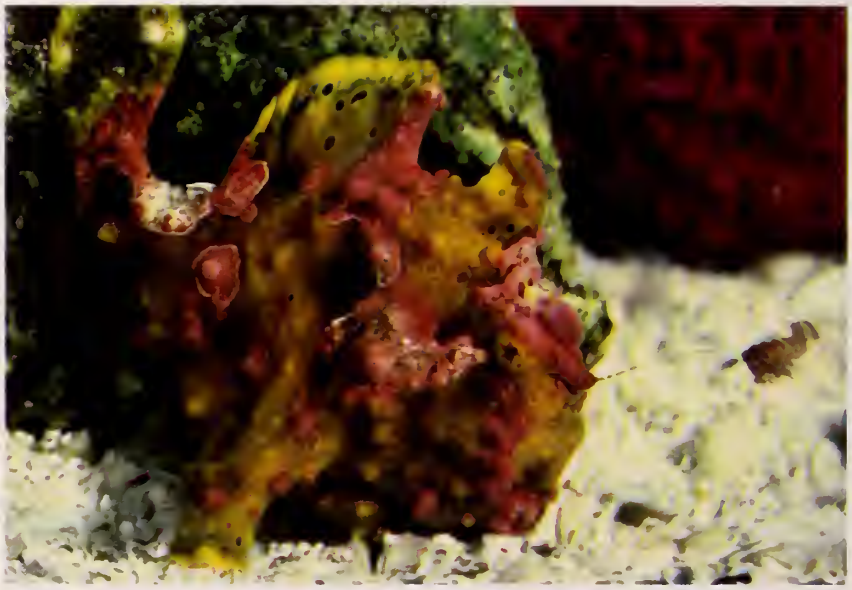


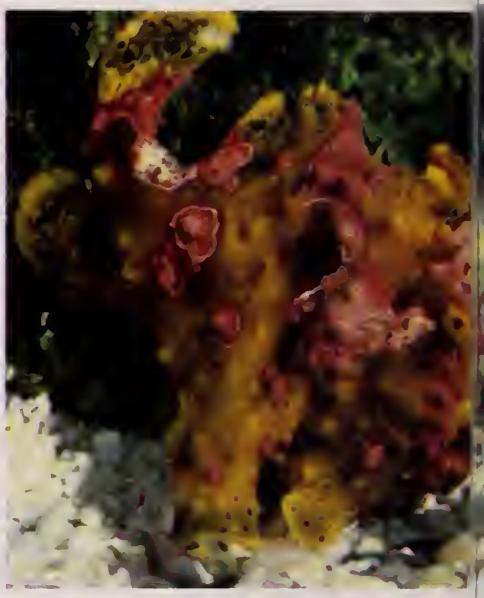
Recovery on the mountain will go on for many years. At first, physical changes will predominate: wind will remove the dust, mud will erode, glaciers may recover somewhat. Many lakes and streams should recover quickly, although the persistence of heavy sediment loads will probably retard the recovery of fish. In the higher forests, snow-protected small trees will form the next generation and provide a forested look to much of the blowdown area within fifteen to twenty-five years. Above timberline, as surviving vegetation emerges from beneath mudflows and ash, only subtle differences from preeruption conditions will be evident. Where high-elevation vegetation was destroyed, however, revegetation will be slow and dependent on long-distance dispersal.

Foresters, ecologists, soil scientists, limnologists, entomologists, and other biologists have coordinated their studies of the biological aftermath of the 1980 Mount St. Helens eruptions. In our efforts to understand how ecosystems recover from such fundamental disturbances, we build on the work of pioneers. What we learn may, in turn, help us develop judicious ways to cope with future natural catastrophes. No one wishes to experience further Cascade eruptions, but should they happen, we will be better prepared to encourage rapid and effective ecosystem recovery techniques. □

With the afternoon sun obscured behind a ridge, fireweed blossoms scatter their luminous message of life among the stumps of an earlier clear-cut operation four miles west of the peak of Mount St. Helens.

Ralph Perry





A world of wonder.
A world of value.
MEXICO
You'd have to crisscross the globe to find all the vacation riches waiting for you in Mexico. In one country, one visit... which we're sure will lead to many more... you'll experience an unforgettable panorama of sights and sensations. Ancient pyramids soaring above lush tropical jungles. The softest white sands melting into turquoise seas. Marketplaces alive with creativity. Fabulous museums. Elegant restaurants.
And our world of wonder goes on. A fascinating land made even more appealing as Mexico maintains its reputation as one of the great travel values. The extraordinary vacation. At a most ordinary price.
Coba... one of the many impressive archaeological zones on Mexico's magnificent Yucatan peninsula is awesome in size and scope. It means "opaque waters" and is located in the state of Quintano Roo... easily accessible from the resort paradises of Concun and Cozumel.

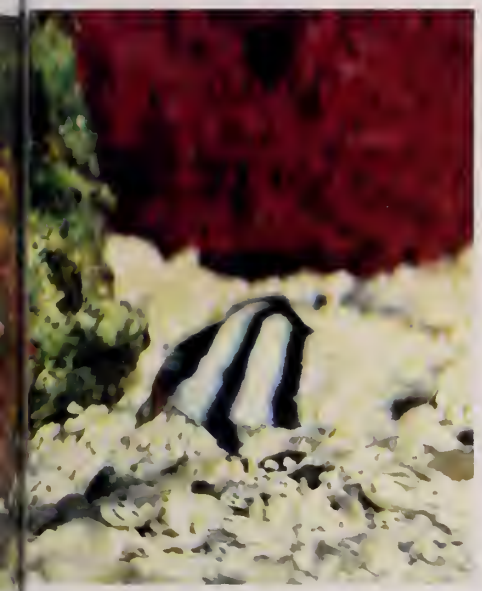
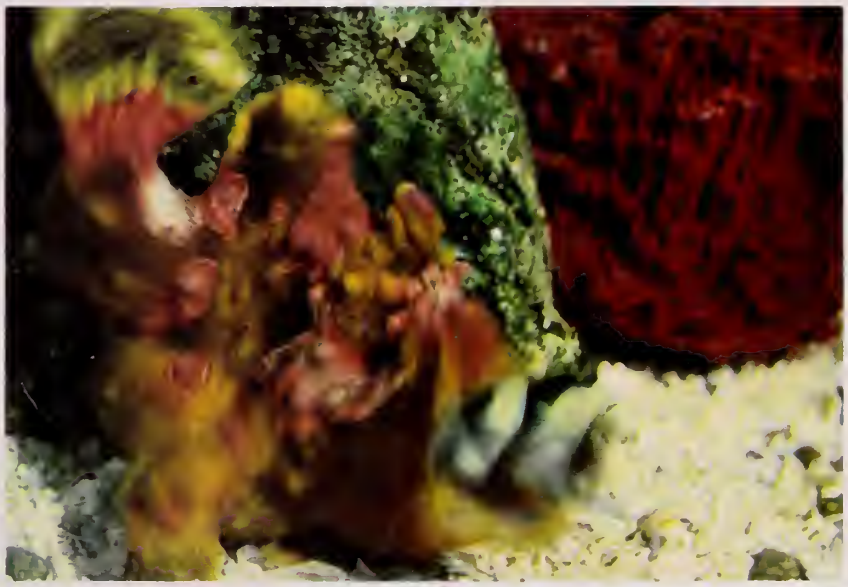
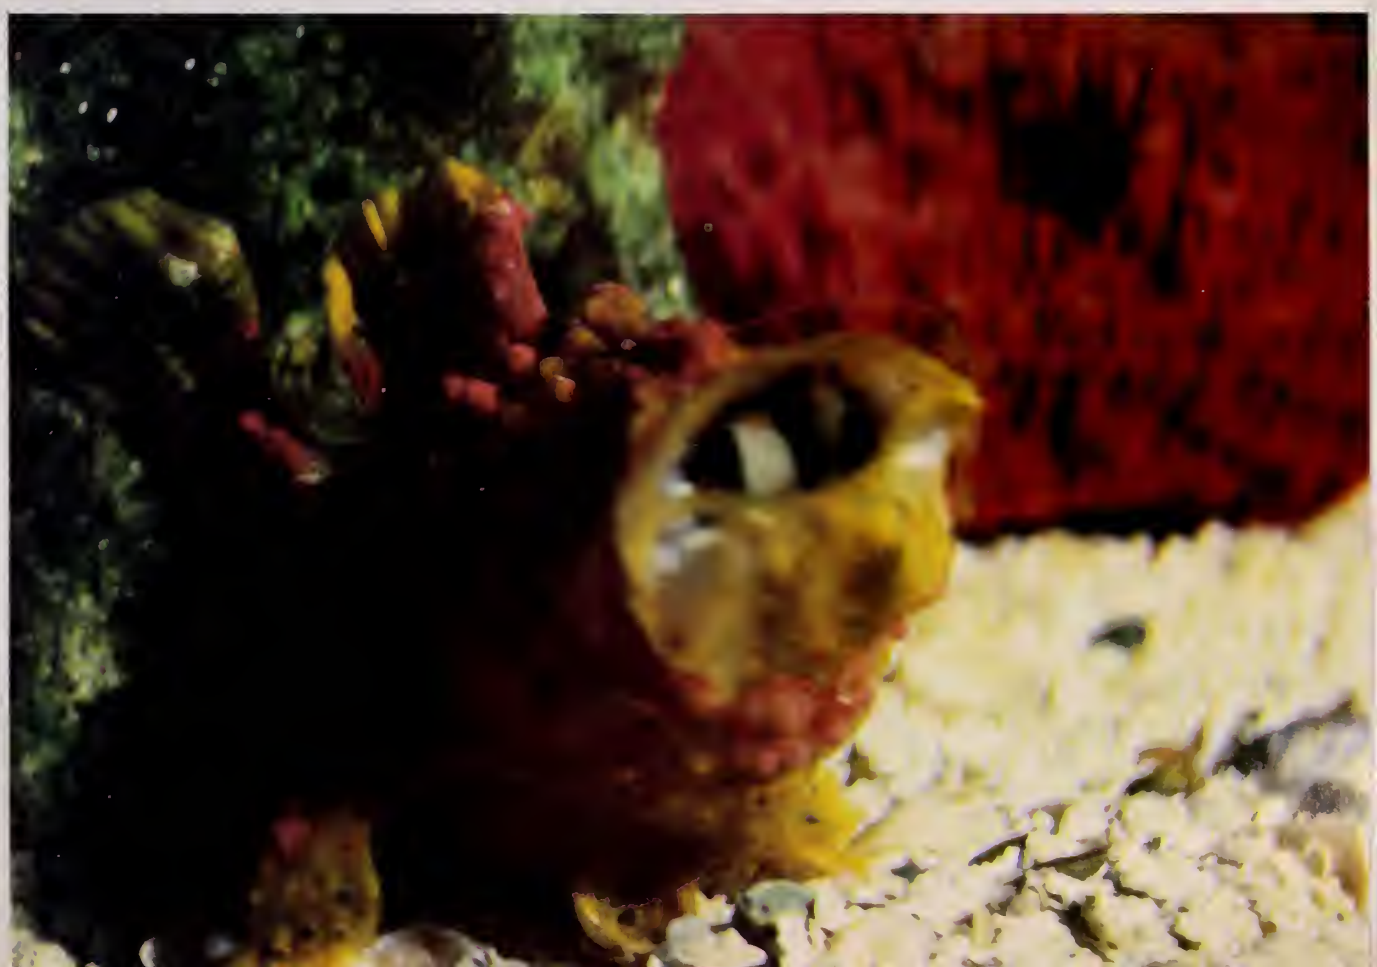
Steady as a Rock, Fast as Lightning

Text and photographs by David B. Grobecker

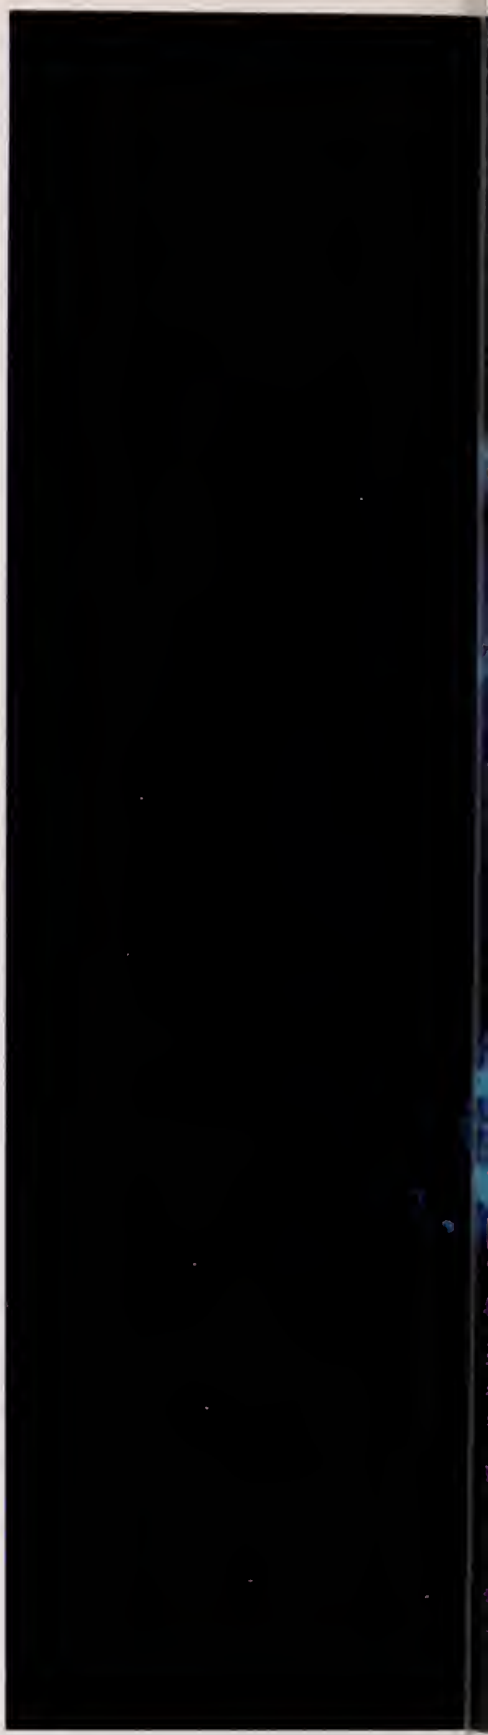




Swimming along a coral enclave in search of food, a small reef fish spots a prey item near a small coral-encrusted rock. The fish moves in for what seems an easy kill, but suddenly it mysteriously disappears. In a matter of milliseconds, this predator-turned-prey has been captured and consumed by a warty anglerfish (*Antennarius maculatus*). The small coral outcropping was in reality the cryptic anglerfish, and the apparent prey was part of a modified fin spine, which the five-inch angler dangled in front of its mouth as bait.



The warty anglerfish, so named because of the wartlike bumps that cover its body, inhabits the coral reefs of the Indo-Australian archipelago. The species belongs to the family Antennariidae, one of sixteen families of the order Lophiiformes, a curious assemblage of fishes characterized most strikingly by the anterior spine of their dorsal fin. This spine is placed on the end of the snout and modified to serve as a luring apparatus. At the tip of the flexible spine, or illicium, hangs a fleshy bait, or esca, which takes many different forms and mimics in appearance and movement such creatures as worms, shrimps, and even small fish. A shrimplike esca, for example, is maneuvered to simulate the quick, backward-darting motion of a swimming shrimp, while a fishlike esca is made to ripple as it is pulled through the water, mimicking the lateral undulations of a swimming fish. (If the "bait" is nipped off, a nearly exact replica rapidly regenerates. Growth is obvious within a few days, and the esca may be fully replaced within two weeks.)



The feeding strategy of these piscivorous fish consists of wriggling the lure while maintaining the immobile, inert appearance of a sponge- or coralline-encrusted rock. When the anglerfish is not luring, muscles inside the esca contract and the illicium is laid back on top of the head in an inconspicuous position. Luring behavior is activated by visual and tactile stimulation. Once the prey is enticed within striking range, the angler suddenly expands its mouth cavity, creating a negative

A warty anglerfish, giving the appearance of an immobile sponge- or coralline-encrusted rock, wriggles a conspicuous lure at the end of a modified fin spine, left. A three-striped damselfish, Dascyllus aruanus, *dashes in and nips at the bait, center. With a sudden burst, the aggressive mimic engulfs the unsuspecting prey in one of the fastest feeding events ever recorded for vertebrates, below. In this rare case, the anglerfish engulfed its own bait and has just released it, bottom, keeping the damselfish securely inside its mouth.*

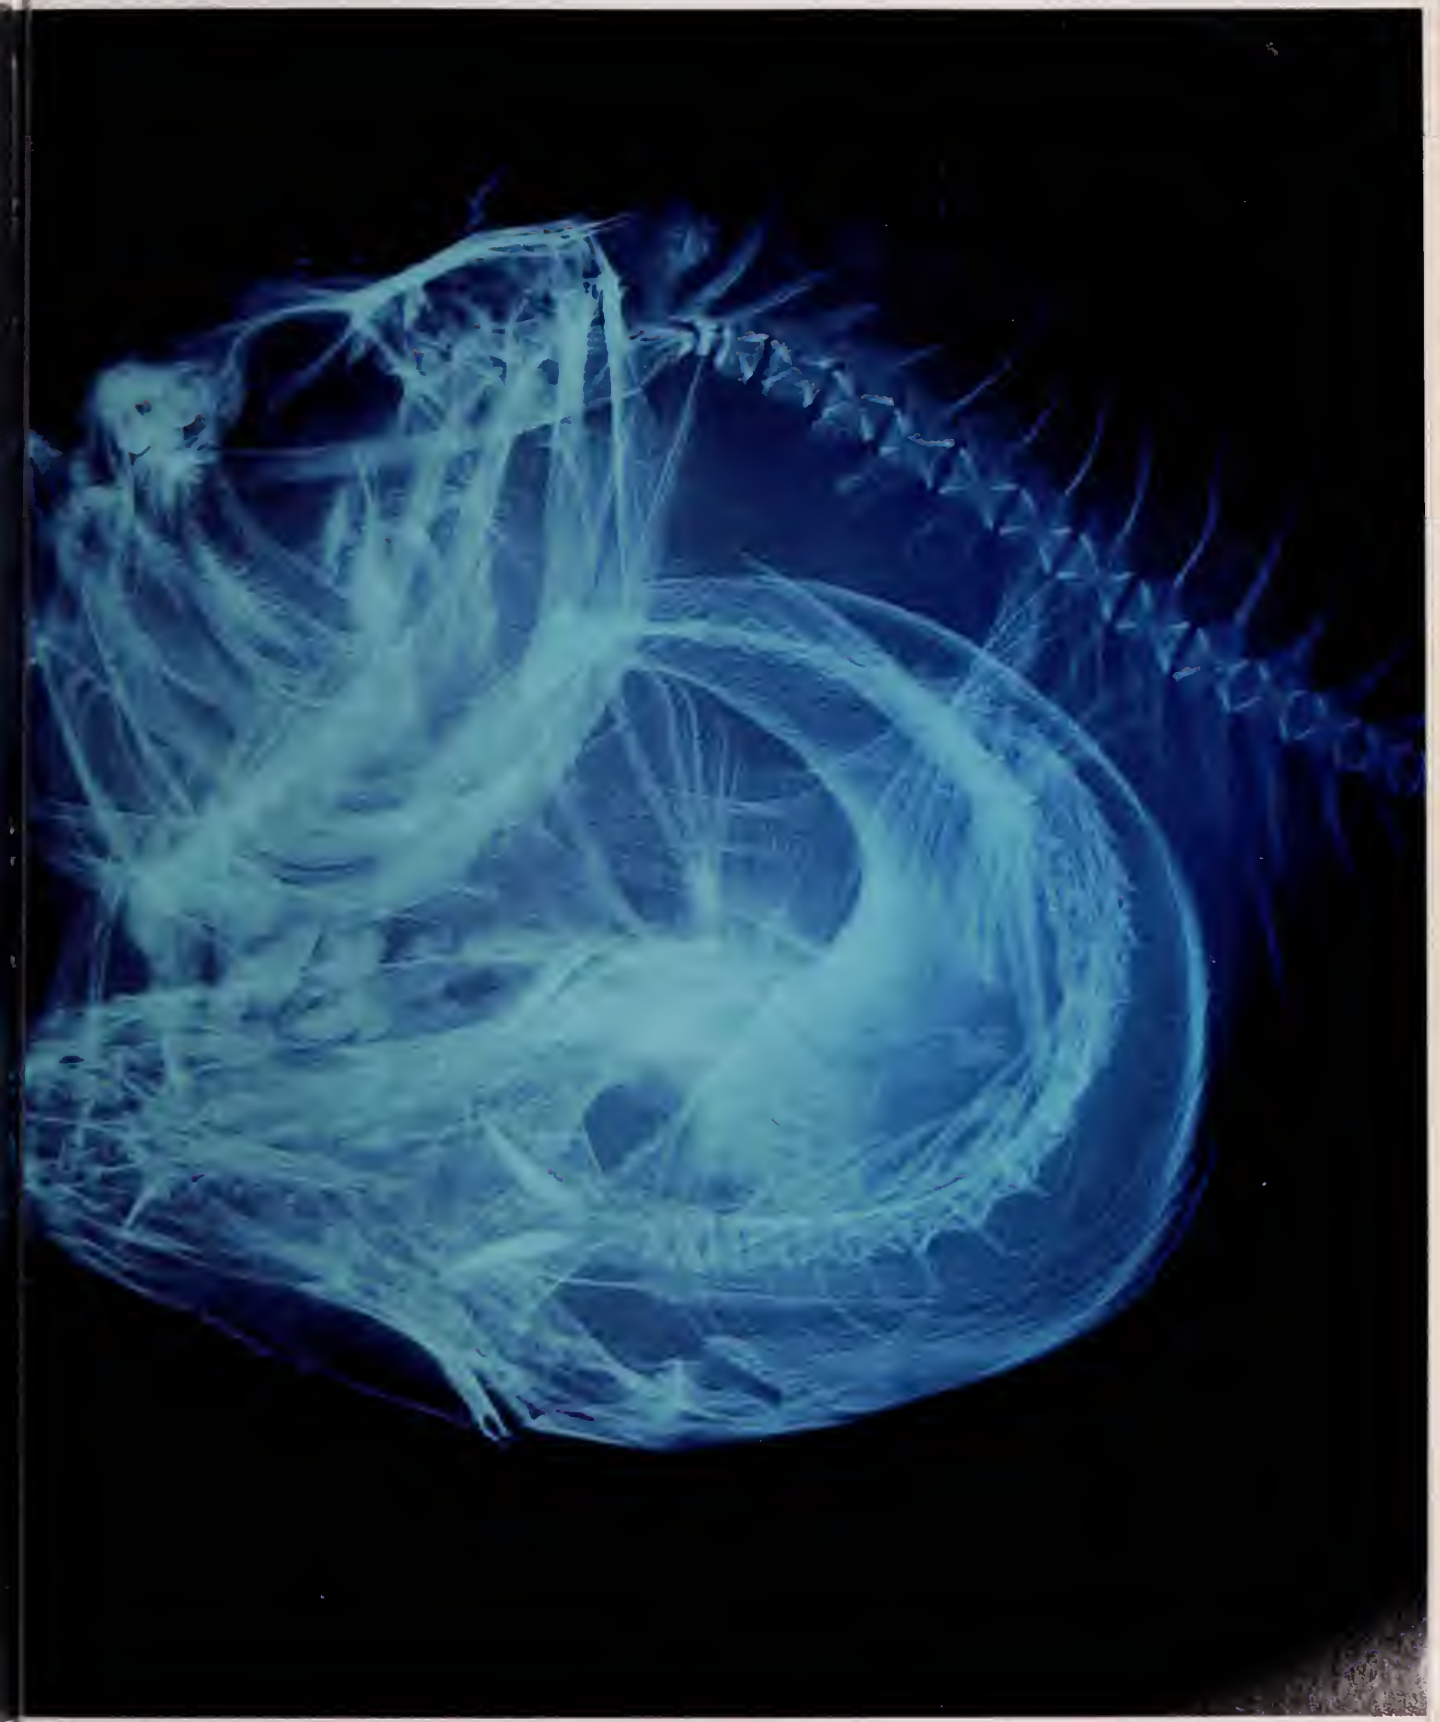
Anglerfish of the genus Antennarius *are able to engulf whole prey with body length considerably larger than their own, as demonstrated in this radiograph of an angler with a scorpionfish in its expandable stomach.*

pressure that sucks in both the victim and a large volume of water. This engulfment is so quick that all a human spectator sees is a blur. But by using high-speed cinematographic equipment to record and later slow the action down, I was able to observe closely the fish's unusual method of feeding.

A feeding warty anglerfish can expand its mouth to twelve times the volume of the mouth when closed. The speed at which it expands its mouth and engulfs its catch is amazingly rapid. Analysis of a film sequence shot at 1,000 frames per second revealed that the warty anglerfish was capable of engulfing prey in fewer than six milliseconds, making it one of the fastest-feeding vertebrates ever recorded.

The anglerfish is able to force an entire prey item directly into its stomach in only about twice as much time as it takes to engulf the prey. Clamping its modified opercular openings shut with its pectoral fins, the fish swallows the entire mouthful of water and prey. After the prey is safely in the stomach, the ingested water is forced out through the front of the mouth and the now unclamped opercular openings. Large prey items, sometimes larger than the anglerfish itself (see radiograph, right), are transported to the stomach in a conventional way, by the raking action of well-developed pharyngeal teeth.

When it comes to diet, the anglerfish is less than choosy. The warty anglerfish is mostly piscivorous but takes an occasional crustacean. The goosefish *Lophius americanus*, recorded to reach nearly four feet in length, is known to have eaten cormorants and herring gulls, while one dissected Sargasso angler (*Histrio histrio*) held sixteen young of its own species inside its huge, expandable stomach.



In 1837, the French naturalist Achille Valenciennes provided an intriguing, if anecdotal, discussion of the foraging behavior of an anglerfish:

> They have the ability to inflate their bodies like a balloon by gulping air or by filling their membranous stomachs with water . . . the position of the paired fins gives them the appearance of having four feet. . . . The tiny gill openings, represented only by a round aperture hidden in the axil of the pectoral-fin lobe, enable them to remain out of water for extended periods of time. This, in turn, enables them to crawl out over seaweed and mud. Thus, they pursue their prey. . . .

The ability to remain out of water is questionable, but these fish do use their armlike and leglike pectoral and pelvic fins to crawl, walk, and even gallop. They have also evolved another form of locomotion unusual for fish: jet propulsion. The anglerfish sucks water into its mouth and forces it out through the long, tubular opercular openings. Then, using its pectoral fins as planing devices and its tail as a rudder, the fish maneuvers about its reef habitat.

Warty anglerfish observed in aquariums aggressively defend their feeding sites against intruding anglerfish. A fish positions its body between its site and the invader, while at the same time engaging in elaborate display behavior. Spread fins, blushed colors, and a gaping mouth are accompanied by an intense shaking of the entire body. This intimidating display is usually enough to repel the unwelcome trespasser, and the anglerfish is once again free to turn into a rock.

The warty anglerfish uses great energy-saving tactics in its quest for food. The combined structural and behavioral adaptations, including the evolution of an ultrafast feeding mechanism, have played an important part in the success of this aggressive mimic. □

Good Dugong, Bad Dugong; Bad Turtle, Good Turtle

The sea provides, and Torres Strait Islanders have a highly discriminating sense of what in the marine larder is good to eat

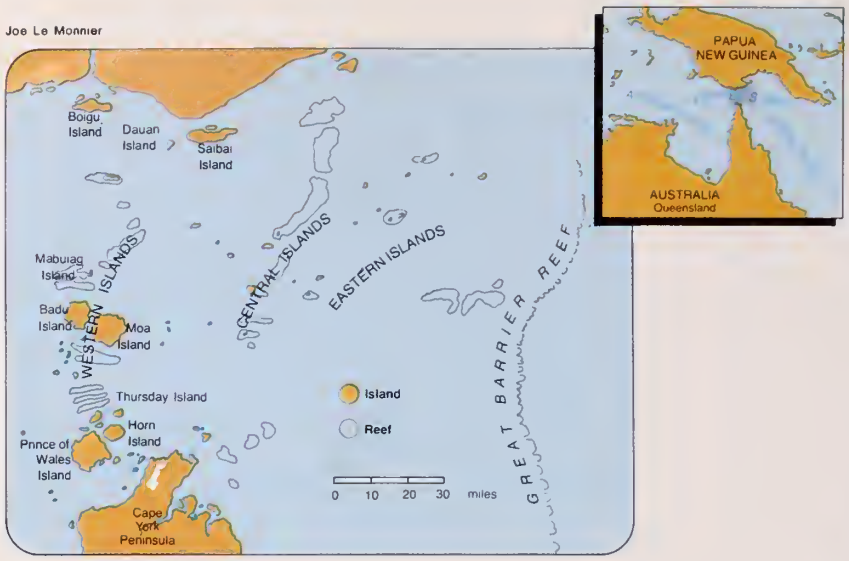
by Bernard Nietschmann and Judith Nietschmann

Bernard Nietschmann

Jumping to add heft to his thrust, this Torres Strait Islander, is about to harpoon a fat dugong. He is aiming for the mid-back of the animal, and strength is needed to penetrate the inch-thick skin.

Paul K. Anderson

The persistence of a marine hunting society—based on large numbers of dugongs and green sea turtles—in the Torres Strait, between Australia and New Guinea, represents an intriguing case of survival. It involves isolation and acculturation, natural and cultural history, legislation and economics, and a set of adaptations by a seafaring people to two elsewhere-threatened marine animals.



Dugongs and green turtles are unique in the sea because they are the only large, economically important, exclusively marine animals that graze on the world's underwater "grasslands"—the sea-grass communities. One link removed from the sun, these two herbivores convert the primary production of vast beds of sea grasses that flourish in shallow, clear tropical waters into abundant, flavorful, high-quality meat and fat. Held in high esteem by many seaside folk, in the past these animals have frequently been among the most sought after sources of subsistence. Many societies in the maritime tropics were once highly adapted to, and greatly dependent upon, these species. Today, however, they are rare, endangered, threatened, or gone over much of their former ranges. Probably the most important major refuge of these animals in the Indo-Pacific occurs along the marine fringes of northern Australia, including the Torres Strait.

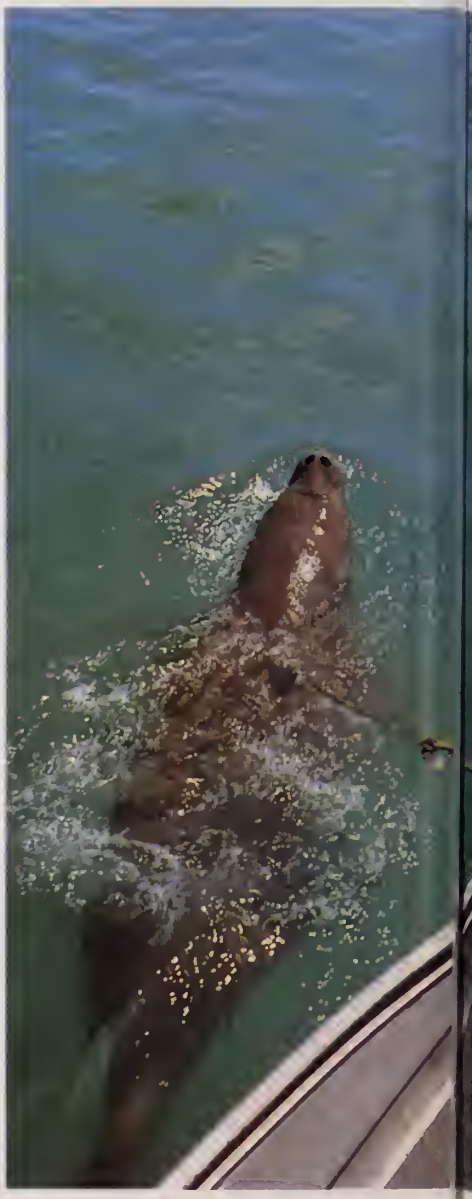
The continuing presence of dugongs and green turtles has meant the survival of the Torres Strait Islanders' hunting activities and much of their culture. Most other tropical marine hunting societies have disappeared, overwhelmed by the spread of foreign colonization, cash market systems, and the loss or depletion of their faunal mainstays. These societies ceased to exist or were altered radically before much could be learned about their specialized cultural adaptations or about their knowledge of animal behavior, accumulated through generations of practical experience. Yet, the Torres Strait Islanders continue to follow old hunting patterns and traditional social customs even though they long have been in contact with outsiders and have adapted to many modern ways. They have adapted new influences in order to continue old life styles. The hunters are dependent on expensive gasoline, motors, and dinghies, but despite the economic costs and the hours at sea in cramped dinghies, they still follow tradition and freely give away meat.

For Torres Strait Islanders, hunting is more than a subsistence trait, a means to acquire meat, or an aberrant relic of past times; it is a way of life. Around marine hunting and the pursuit and capture of large herbivores revolves a complex system of logic and knowledge, environmental perception, social expectations and responsibilities, and the resilient roots of Islander myths and legends. The result is cultural adaptation to the coming of modern times to a once sequestered group of islands and people.

The Torres Strait area is Australia's "marine outback." Isolated and frequently cut off from the mainland by difficult environmental conditions and poor local transportation, it is a thinly populated and little developed region.

Joe Le Monnier

Some 4,500 Melanesian people inhabit seventeen of the myriad islands, thirteen of which are reserves; about 2,000 Islanders, and 1,000 other people of multiethnic backgrounds, live on minuscule Thursday Island, a nonreserve island and the region's only commercial and administrative center. The reserves are administered by Queensland's Department of Aboriginal and Islander Advancement (DAIA) and subject to a special set of state laws known as "the Act."



Within a span of little more than 100 years, this area has experienced many external influences: the introduction of Christianity and Mother Hubbard dresses brought by the London Missionary Society; several boom-and-bust economic cycles focused on pearl shell, trochus shell, and *bêche-de-mer* (sea cucumber), which introduced wage labor, cash-based economic exchanges, dependency on market goods, and South Sea Island males to supplement local labor; the influx of 6,000 Japanese pearl shell divers between the 1870s and 1940 (1,200 of whom never finished their six-year contracts, having died in the Torres Strait while pursuing their dangerous occupation); cursory bombing and the threat of invasion during World War II and the mobilization of Islanders into an army unit; and postwar increases in Commonwealth and Queensland State expenditures for new housing, medical care, and social benefits.

In the face of the kaleidoscope of introduced new ways and materials, the Islanders have maintained much from their past by recasting outside influences with Islander molds. All activities are dominated by kinship and social obligations. For example, even though traditional death ceremonies have been changed to accommodate introduced Christian rituals, the obligations of the living to prepare the way for the dead still follow traditional beliefs and kinship-based duties. Similarly, Islanders continue to hunt, not because they have to, but because they want to.

Queensland State legislation allows continued subsistence hunting of dugongs and sea turtles by Islanders (and Aborigines) living on reserves. The reserves represent both oppression and protection. The government controls the finances and most of the transportation and communication for the reserves. While some of the things an Islander can do are restricted because of the reserve legislation, Islanders can restrict outsiders from visiting the reserves. Islanders can travel between the reserves and to the mainland, but outsiders cannot go to the reserves without special permission. This must be obtained from the elected Islander chairmen and councils, which administer much of the internal affairs of each locally governed community and strictly limit and control the intrusion of non-Islanders. Thus, despite the presence of such conveniences as radios, tape recorders, hand-cranked sewing machines, outboard motors, tinned and sacked foods, and State and Commonwealth social benefits, the Torres Strait Islanders remain one of the foremost tropical marine hunting societies in the world.

Within the Torres Strait, dugongs and green turtles are concentrated in the waters surrounding the high, granitic Western Islands and to a lesser extent the low, coral Central Islands. Around these islands, the seas are shallower, the coral-rimmed reefs and sand shoals more abundant, and sea grasses more plentiful than around the volcanic Eastern Islands. The major hunting areas are concentrated over the numerous big reefs around Mabuiag, Moa, and Badu islands.

Dugongs and green turtles are dependent upon, and exert a considerable pressure on, beds of sea grasses and some algae. Pasturage and tides influence feeding time and place. During high tide the animals move to inshore areas and the higher, windward-side reef tops; during low tide they move to offshore, deeper water,

Exhausted and dying, a harpooned dugong is pulled to the boat, below. After a successful dugong hunt, carcasses are laid out on the beach, right. A dugong is butchered by the man who harpooned it, one of his mother's brothers, and select members of the hunting crew. Adult females are the most prized dugongs because they are fattest. Males are hunted when there are no females in the vicinity.

Barney Nietschmann, Jr.

Bernard Nietschmann

leeside reef zones. Daily grazing amounts are estimated to average 80 to 100 pounds for an adult dugong and 10 to 15 pounds for a large green turtle. Except for *Halophila*, found in sheltered intertidal island flats, the commonly grazed sea grasses, such as *Thalassia*, *Thallasodendron*, and *Cymodocea*, do not occur in dense single-species stands. Instead they are found mixed and scattered over large areas depending on depth, type of bottom, and exposure. Any one particular sea-grass bed cannot support long-term grazing; therefore, sea-grass availability, density, and recovery rate are the most important factors determining the presence and movements of dugongs and green turtles.

Seasonal and episodic fluxes in environmental conditions also significantly affect herbivore presence and movements and, accordingly, the timing and predictability of hunting. Tidal ranges and currents, water turbidity, and wind intensity and direction all influence temporal and spatial distributions of dugongs and green turtles. Extremely strong tidal streams (frequently six to seven knots and even more in narrow channels between reef sets), an eleven-foot tidal range, intermittent days and weeks of turbid and clear water, and two main seasons dominate marine conditions and herbivore habits.

Dugongs are highly sensitive to tidal fluctuations and changes in water clarity. Moving from place to place, they often swim with the flood and ebb tides. Some sea-grass beds are so shallow that they are dry at low tide; dugong feeding is thus limited to high-

tide periods. Since most hunting takes place in water two fathoms or less in depth, the large tidal range alternately opens and closes vast hunting areas. When strong winds coincide with fast tidal currents, the water becomes turbid and underwater visibility is often no more than three feet. Dugongs appear to prefer turbid water, which by making detection difficult offers them protection.

The southeast trade wind season, from about May through September, is the time of little rain, clear skies, gusting and heavy winds, and moderate to rough seas. Low tides and scattered animals make hunting during the day difficult. It is better at night when the high tides bring dugongs and green turtles to the reefs and island margins. A two-month-long period of calm weather follows, with light north winds, dead-calm sea, and good hunting conditions, both at night, when the herbivores can be spotted by trailing streams of bioluminescence, and during the day, when they can be easily seen in the clear waters. The rainy season lasts from December through April. This is the northwest monsoon season; frequent squalls, storms, and heavy winds often preclude distant hunting ventures. But there are many days of calm, and due to daytime high tides, hunting is generally much better than in the southeast trade wind season. The most favorable, but difficult, hunting conditions occur when a northwest storm lashes the reefs, driving large numbers of dugongs into leeside island shelter where they feed in the turbid water.

Dugongs live in loose social groupings whose size fluctuates periodically, depending on reproductive behavior, food supply, environmental conditions, local- and long-distance movements, and hunting pressure. Most dugongs we observed traveled in pairs—adult female and male or mother and calf—and in small groups of fewer than ten that included young, sexually mature, and old animals. Herds of more than twenty are rarely seen in the Torres Strait except when small groups gather together to shelter from a storm. At least some dugongs (called *malu dangal*, or "deepwater" dugong, by the Islanders) appear to travel long distances seasonally and may be migratory. Other dugongs seem to reside in large reef and island margin territories.

Even though dugongs are hunted year-round in the western Torres Strait, they are still numerous, probably as a result of protective legislation, possible recruitment of animals from even more isolated populations, frequent moves to reefs too distant for the hunters, and reduced hunting pressure due to post–World War II Islander emigration to the mainland (to seek employment and education). Around Hammond, Thursday, Moa, Badu, and Mabuiag islands, dugongs have been so abundant recently that they have clear-grazed extensive areas, causing Islanders to complain about the reduction of grass-habitat fish.

Of the four species of sea turtles found in the Torres Strait, only the green turtle is hunted with any regularity; the hawksbill, loggerhead, and the endemic Australian flatback are seldom hunted or eaten. Green turtles exhibit complex daily and seasonal movements that redistribute their numbers in and among foraging areas. They also make periodic migrations to nesting beaches—Bramble Cay at the northern edge of the Great Barrier Reef and Raine Island farther south. Nesting cycles overlap and probably occur at two-, three-, and four-year intervals; these may be influenced by ecological factors. Despite hunting pressures there are still large herds of green turtles in the Torres Strait, and this area, along with the rest of the waters off the Queensland coast, makes up what is perhaps the most important green turtle territory in the world.

In 1976, we began studying how the Islanders perceive and categorize the marine environment, and how their concepts correspond to the behavioral ecology of dugongs and sea turtles and influence hunting patterns. Local names for marine biota, features, places, and marine conditions were taught to us by the hunters during trips at sea. What began to emerge was a complex and detailed taxonomy. For miles around, the Islanders' underwater world is seen as clearly as if it were dry and readily open to view. There are names for large and small reefs, even for coral heads, dugong "scratching rocks," shoals and sand bars, shallow and deep areas, narrow, twisting passages or channels through reefs, sea-grass feeding areas, and various zones on the reefs where particular fish, crayfish, turtles, and dugongs can be found. The Islanders have a detailed, logically consistent system of knowledge and theory that integrates human and natural spheres into one ecological unit and permits them to make pragmatic hunting decisions in an oscillating marine environment.

A detailed and exacting classification system for marine features and biota is to be expected from a seafaring people. But it is in the understanding of tides and associated dugong and green turtle behavior that Torres Strait Islanders excel. According to the hunters, "Everything move on tide—fish, turtle, dugong. Everything. You have to know these things—these tides." We were taught more than eighty terms for different tides and tidal and water conditions. A few examples should give an idea of the complexity of their perception of tides and associated water condi-

Butchering is a complex process, as well as a highly social event. Lines are sliced into the dugong's hide to serve as cutting guides, above. At least forty-five different cuts of meat can be carved from a dugong. After the harpooner, his crew, and his mother's brothers receive their favorite pieces, other households in the village share what remains. This distribution of free meat brings prestige to the hunter. The bounty of the hunt is often cooked right on the beach, right.

tions: *kukiau gi iabagar* is a northwest season, daytime, big high tide; *mugi batainga ura* is an early morning, strong, clear-water, west to east tide; *kadigad* is a long, clear-water, slack tide between two neap tides; and *kutau usalai* is an afternoon, strong, dirty-water, west to east tide that occurs two to three days after new and full moons. There are good and bad tides for hunting turtle and dugong. Even if the villagers "feel to eat dugong," the hunters won't go out if the tidal conditions are wrong.

Of all the marine fauna, dugongs and green turtles are the most precisely described. There are terms for different ages, sexes, sizes, ranks, colors, social groupings, and taste qualities: a total of twenty-seven different terms to distinguish dugongs and thirteen for turtles. Taxonomy for dugongs corresponds closely to Islander categories for age, sex, and social rank (for example, female child, female teen-ager, single adult female, pregnant female, nursing mother, grandmother).

In dirty-water conditions, the hunters can often tell the size and sex of a dugong from its wake and position in a small or large herd. The most sought after and esteemed dugongs are the fatter females, particularly pregnant ones and those seen mating or feeding and traveling with a male. Wakes, heads, surfacing and diving postures, and herd position are difficult to discern at night. To distinguish age and sex, the Islanders often rely on the exhalation sounds dugongs make when they surface to breathe. Surfacing turtles and porpoises are often found on the reefs and add their own noises. When one of us, Bernard, first went with the hunters at night, turtle, porpoise, and dugong exhalations all sounded similar to him. After several hunts, he could tell the difference among them, but all dugongs continued to sound alike. Eventually, he began to volunteer guesses on whether a dugong was female or male. This was not a great breakthrough in perception as he had a 50–50 chance of being right. The hunters, however, seldom made a mistake. *Ipika dangal* ("female adult dugong") they'd decide and go after it. If they could not hear or approach a female closely enough, they would go for a male.

Bernard Nietschmann

A hunter cannot bring just any dugong or turtle back to the village. The animal must be fat, and it must have the right kind of fat. The Islanders have a very refined taste for meat and fat, which are inspected and savored to the extent that wines, cheeses, or cigars might be in another society. A *wati dangal* is a "bad dugong" and has a thin and "silky" layer of fat. It is considered almost inedible. The Islanders say that if you were to eat the meat of a *wati dangal*, it would have a bad taste and make your belly ache. Similarly, a *gatau waru* ("reef-dwelling green turtle") has bad fat—thin and black in color, not the thick and green fat of a really good turtle, or *mina kapu waru*. Both *wati dangal* and *gatau waru* are quite common around the islands and reefs. A hunter must be able to recognize their physical and behavioral characteristics so as not to harpoon one by mistake. The Islanders also say that the meat and fat from most male green turtles are poor tasting. When dugong and turtle meat are "proper fat," everyone is thankful. "When we eat good fat dugong we feel happy," one hunter told us.

Islander hunting strategies reflect their discriminating tastes. Small turtles and dugongs are not as fat as large ones and so are hunted infrequently. *Wati dangal* and *gatau waru* are generally left alone. Male green turtles are less fat than females and are seldom hunted. Huge turtles and dugongs are rarely sought because the small size of the dinghies makes it difficult to get back home with so much added weight. The hunting pressure focuses on the middle age-grades of *malu dangal*—the hardest to catch

—and on medium to large female green turtles.

Dugong and turtle hunting is a major activity for many men, and meat from these animals provides the most important and dependable source of protein to villagers in several island communities. Although all men consider themselves seamen, not all are hunters. A real hunter is called a *buai garka* (literally, "male family head"). In any dugong- or turtle-hunting party he is the leader, the harpooner, and the one who makes all the decisions. A *buai garka* is a respected person. "He knows how to hunt, how to find dugong, how to spear." It takes a long period of training and experience to become a good hunter. One has to master a complicated body of knowledge that includes the animals' behavior, the precise times and places to hunt, the difference between various types and qualities of animals, and the way to get close enough to a dugong or turtle to harpoon it.

Teen-agers start by going along as crew to help paddle and to pull harpooned animals alongside the dinghy. During the hunt, the *buai garka* will usually tell them about tides and dugong and turtle behavior. But to teach how to harpoon and to have luck is the role of one of a boy's mother's brothers (*audi*). When the novice is strong enough to handle a fourteen-foot harpoon, he is taken out for lessons. The first dugong that he catches is given to his *audi*. In addition, the boy's parents must provide a selection of gifts for the *audi* to choose from. The training and hunting relationship between a boy and his mother's brother conforms in structure and nature to traditional initiation rites that were discouraged many years ago by missionaries.

As much of the hunting takes place in turbid water conditions during the northwest season and at night during the southeast season, the hunters must rely on several clues to find their submerged prey: floating sea grass uprooted by dugongs as they feed; milky white sand and silt clouds in the water made by dugongs as they uproot the grasses; floating excreta; and wakes, swirls, and bubbles on the surface. The animals can be easily seen when they surface for air, but to get within harpoon range, the hunter must estimate the drift rate of his boat, anticipate the feeding interval time, and be able to distinguish the dark form of a submerged dugong from rocks, coral heads, and feeding turtles. He must also make sure that the animal is not a *wati dangal*, which has a thinner shape, more prominent backbone ridge, and rougher-appearing head than a good dugong. If he under- or over-estimates drift speed and direction or submerged feeding intervals, the dinghy will be too far away to use the harpoon. If he mistakenly harpoons a bad dugong, the entire effort has been a waste of time, and the noise from the struggling animal will frighten off other dugongs in the area.

Even with the proper training and experience, a hunter is far from assured that he and his crew will get a good dugong or turtle. Much depends on luck. Bad luck in hunting can be caused by people in the village

Green sea turtles are not as desirable to the hunters as dugongs, but more turtles are taken because they are easier to catch, above. Females are sought because the males are considered poor tasting. The meat from green sea turtles and dugongs provides the bulk of the protein intake for many villages in the Torres Strait. Hawksbill turtle eggs, right, provide a supplement to the Islanders' primary diet.

"talking bad" about the hunter, by wasting meat or allowing some to spoil, by being selfish and not giving enough meat to people in the village, by taking someone along as crew whose wife is pregnant, by having sexual intercourse the night before the hunt (this last belief is an old one, however, and not all hunters still practice sexual abstinence prior to a hunt). On the other hand, good luck can be encouraged by sprinkling salt on the harpoon line, by always giving meat to one's *audi* and asking him to help butcher, and by making a visit to the graveyard to ask ancestors for luck. Certain plants, ashes, and charms can also be used to attract dugongs and turtles, but these are personal secrets, and hunters do not readily talk about them.

Hunting is reliable, productive, and selective. During our research on Mabuiag Island, hunters returned with a turtle or dugong 75 percent of the time. Even though dugongs are the objects of most hunts, more green turtles are taken because of the comparative ease with which they can be captured. Dugongs, however, are more challenging, provide more meat and fat, and are considered better eating than green turtles. Hunting pressure from different island villages is predicated on population size and on such economic and social factors as availability of dinghies and motors, number and frequency of feasts (birthdays, baptisms, weddings, funerals, dinghy blessings), household purchasing power (for gasoline and oil), and environmental conditions (wind, sea, tide, and associated dugong and turtle movements). There is considerable variability in subsistence hunting from island to island.

Bernard Nietschmann

Butchering of dugongs and green turtles is a formalized social event. Women, children, and village men who did not participate in the hunt congregate on the beach to watch and comment loudly on the quality of the fat and the size of the animal while they await their portion. Three or four men will butcher a dugong or turtle: the man who harpooned the animal, one of his mother's brothers, and one or two members of the hunting crew. Young boys help by washing pieces of meat in the sea. A complicated system is followed for butchering a dugong. Lines are scratched into the thick hide to act as guides for cutting. The number, names, and placement of these cutting lines have not changed since the first ethnographic descriptions were made in the late nineteenth century. There are at least forty-five names for different cuts of dugong meat, and about thirty for turtle.

An adult dugong usually weighs from 500 to 750 pounds, 30 percent of which is considered edible; a green turtle generally yields 45 percent of its average weight of 250 to 350 pounds. Reducing these large animals to many small piles of specific pieces prior to distribution is physically demanding but socially enjoyable. It is a time for everyone to visit, joke, and share the story of the hunt.

Favorite pieces are given to the person who harpooned the animal, the members of the crew, the butchers, and the harpooner's mother's brothers. The rest of the meat is shared equally and freely among all households if there is enough. If the amount of meat is insufficient, the harpooner, in consultation with his *audi* and other elders, decides who will receive meat. Theoretically, households that were not given meat from a previous butchering are the first to receive. Waste is thrown into the sea where swarms of sharks quickly dispose of it. One man told us that it is an Island custom to feed the sharks with waste from a butchering: "We always give them something, turtle or dugong. They know we live from the sea just as they do."

People would eat more meat and fat if they could. If the annual Mabuiag dugong and turtle catch were divided equally among all the members of the community throughout the year, each person would receive about one

pound per day. If fishing and reef-foraging figures are included, then the total would be 1.2 pounds per person. However, rough weather, bad tides, dugong and green turtle movements, and scarce and costly gasoline limit hunting, and social relationships determine distribution. So the Islanders do not eat meat every day, but when they do, they eat large quantities. In one extreme instance, some 1,300 pounds of butchered dugong meat were distributed in Mabuiag to villagers and to visitors from Badu Island, giving an average of 10 pounds to each person. The meat was gone at the end of the second day of heavy eating.

It costs money to hunt. Outboard motors cost from $800 to $1,600, aluminum dinghies are $1,200 and more, and gasoline (as of September 1980) is $3.00 per gallon. The hunter and his household incur all these costs. Yet, in what is, in part, a monetary economy, they give away meat freely, as hunters always have. Exchange of fresh meat is essentially a social transaction, dependent on kinship ties and independent of cash value or production costs. Purchase of food is reserved for store products, with purchasing ability dependent on household composition and income. Traditional foods are exchanged between households; introduced foods are purchased and normally consumed within separate households. The most desired foods cannot be purchased—fresh meat and garden crops must be given. The capture of each dugong and green turtle, and the butchering and distribution of their meat, validate and maintain social relationships and roles, thereby insuring continuation of "proper Island custom" and solidarity.

Nutritionally, a hunting household is somewhat better off than a non-hunting household. Economically, it is often worse off because so much money is tied up in the dinghy, the motor, mechanical repairs, and gasoline. Socially, it is much better off. A successful hunter gains prestige because he provides the most esteemed items in Islander diet, gift exchange, and feasting. A single kill yields a meal for many households. But hunters don't go out to sea just for prestige. There may be pressure from relatives and members of their own household, especially the women, when people "feel to eat fat meat." A feast may be planned, and a dugong and a turtle should be served to make it a "number one" feast. And there are deeper and less immediate reasons for hunting. Staying around the village can be irksome, and hunting in small dinghies in rough seas for large animals is exciting and challenging. Hunters hunt despite the high costs because they receive personal and social satisfaction from their highly developed skills.

To be a hunter of dugong and green turtle is to participate in a social and perceptual affirmation of being an Islander. To hunt for meat maintains many of the old traditions and beliefs and gives meaning to existence for a people who have chosen not to interact directly in a large, developed, commercialized society and economy. □

An earth oven is used to cook green sea turtle meat, above. Islanders are extremely fond of meat, and the preparations for a feast, right, help to build anticipation for what is to come. The amount of meat consumed during a feast can be prodigious. At one celebrated bash on Mabuiag Island, 1,300 pounds of dugong meat was distributed to the villagers and to visitors from Badu Island. The largess, which averaged 10 pounds per person, was gone in two days.

A Martin House Is Not a Home

People erect elaborate accommodations for nesting purple martins to share. But the birds haven't learned to be good neighbors

by Erik J. Bitterbaum and Charles R. Brown

John James Audubon once remarked that he could always judge the quality of a roadside inn by the condition of the purple martin house erected on the inn's signboard. Good bird accommodations usually meant good people accommodations.

Audubon's observation illustrates the longstanding interest that people have had in the large, purplish swallows known as martins. The first nest boxes in this country were gourds hung by Indians to attract martins. In the 1800s, slaves in the South continued the practice of hanging out gourds. The assumption that martins will chase many species of hawks provided a utilitarian motive for such early martin houses: I offer you a nesting place; you protect my poultry. We feel, however, that the martin's propensity to chase birds of prey has been greatly exaggerated. They do, however, consume large amounts of insects.

Today, in neighborhoods across the eastern United States, martin houses of all makes and models can be found. Birdhouse manufacturers, in promoting their product, proclaim that the purple martin is America's favorite backyard bird. This claim may be more hype than reality, but the purple martin is probably the only North American bird to have its own newspaper. In the *Nature Society News*, published by a birdhouse-manufacturing firm in Griggsville, Illinois, martin fanciers report on their experiences with these birds.

The purple martin (*Progne subis*) is one of five species of the New World genus *Progne*. The other four species—the gray-breasted, Caribbean, southern, and brown-chested martins—are found almost exclusively in the American tropics.

Male purple martins, when about one and a half years old, attain a deep, glossy purple plumage over the entire body and are the only dark-bellied swallows of North America. Females, while having purple backs and crowns, are gray on the throat, breast, and belly. A first-year male resembles a female, except for a generally darker back and a lined patch of purple on its throat, breast, and belly.

Purple martins have a wide but patchy range throughout eastern North America. They also breed along the California coast, in the southwestern desert of the United States, and reportedly, in northern Mexico but are largely absent from the Rocky Mountains except for small, local montane populations. Because martin houses are not prevalent in the West, the

Occupying the topmost tier of a multilevel birdhouse, these purple martin nestlings are protected from the interference of neighboring juveniles by the roofline that separates the nest compartments.

Alfred A. Francesconi

birds there depend largely on abandoned woodpecker holes.

Purple martins migrate through Central America and the Caribbean to the Amazon River basin of Brazil, where they winter. Their annual arrival in the United States begins in late January in Florida and Louisiana and continues through May, farther north. Early arrival time may be related to finding a nesting cavity, a problem encountered by hole nesters that do not excavate their own cavities. Early arrival probably resulted from intraspecific competition for nesting sites, a behavior that evolved before humans provided martins with birdhouses. When the only nesting sites available were unused tree cavities, competition for sites was probably intense. If early arriving birds got the best or the only cavities, and as a result raised the most young, then arriving early could be selected for. A counterbalance to an increasingly early arrival in breeding areas is the probability that early birds will face periods of cold weather and starvation, and thus extremely early arrival could be selected against.

When purple martins nested largely in abandoned woodpecker holes (as the small western populations still do), they were probably mainly solitary nesters. This statement is supported by two kinds of evidence. First, before men and birdhouses came along, colonies of martins would have been possible only where woodpeckers had excavated a number of holes close together. However, most woodpeckers in the eastern United States that excavate cavities large enough for purple martins to use are solitary-nesting woodpeckers, and it is improbable that they bore and then abandon enough holes in any single tree to allow colonies of martins to form. Acorn woodpeckers (*Melanerpes formicivorous*) in the West are colonial and do dig many holes close together, but their extreme aggressiveness around their nesting sites prevents martin colonies from forming there.

Second, purple martins are not able to recognize their own young. This is strong evidence that they originally were solitary nesters. Biologists believe that whenever there is a chance that young of different parents may get mixed up, such as in dense colonies of birds, selection is intense for chick recognition so that an individual par-

Dana Downie

Howard Worthington, a farmer in Pleasantville, Iowa, who built this birdhouse for purple martins, left, about fifty years ago, reports that in the last few years he hasn't had many residents.
A skyscraper for purple martins, below, was constructed in the mid-1960s by the Jaycees of Griggsville, Illinois. The elaborateness of the structure, and the extravagant claim of mosquito consumption, are in keeping with the town's boosterism of these birds. The self-proclaimed "Purple Martin Capital of the World," Griggsville plays host to about as many martins as it has inhabitants—roughly 2,000.

Bill Thomas

ent does not assist the young of competing adults. As a result, chick recognition has evolved in most colonially breeding animals. Not being able to recognize their nestlings is a trait purple martins share with the related and solitary-nesting rough-winged swallow (*Stelgidopteryx ruficollis*).

What could have caused purple martins, at least in the eastern United States, to abandon their largely solitary life style and become a colonial backyard bird? This was probably brought about by the original clearing of much of the eastern forest, which eliminated many natural nesting sites, and the erection of birdhouses, both of which began in the early 1800s. This massive environmental perturbation essentially changed the nature of the purple martin's available nesting

Treat Davidson, Photo Researchers

sites in the southern and eastern United States. Multiroom birdhouses are especially conducive to coloniality because they contain many nesting sites in proximity. Single-room birdhouses are rarely built for martins, and when erected are quickly appropriated by other species; as a result, in many martin populations, solitary nesting seldom seems to occur.

Humans have provided these birds with many housing opportunities, and this has probably caused an overall increase in martin numbers. Yet all is not rosy for martins that nest colonially in birdhouses. For instance, spatial interference between neighboring purple martin pairs is common, owing to the parents' inability to recognize their young. Juvenile martins, when within one to four days of fledg-

Above: One purple martin fancier has expanded on the old Indian and slave practice of hanging gourds for the nesting birds. Right: Located near Tottenville, Staten Island, this complex reputedly houses the only active purple martin colony within the city limits of New York. The housing development for birds was set up by Howard Cleaves.

Anne Heimann

ing, often come out on the birdhouse porches. Since in many martin houses all rooms on a tier are connected by the same porch, the young may mix extensively and move between nearby compartments. Older nestlings cause much disturbance among the birds nesting on a tier, and when they try to enter nests containing eggs, they are often knocked off the porches by the occupants of these nests. These older nestlings sometimes successfully intrude into neighboring nests and usurp most of the food brought by parents of the younger nestlings. On one occasion, one of us observed a nearly grown nestling from one nest enter an adjacent room in which the young had just hatched. The pair in that room promptly abandoned their newly hatched young, which later died, and fed the intruder, which rapidly gained weight and remained in the nest for four days until it fledged. Young birds from adjacent-nesting pairs are most frequently involved in these disruptions, but all pairs that use rooms opening on a common porch are affected.

Besides providing nesting sites, people have also provided martins with some exotic nesting-site competitors. House sparrows and starlings were unwisely introduced into North America and have spread phenomenally from coast to coast. Both species use holes for nesting sites and appear to relish martin houses. Rarely is a martin house not also occupied by house sparrows, and starlings are a problem in some areas. These species fill martin-house rooms with bulky straw nests and sometimes actively chase purple martins away. Bluebirds and wrens also often usurp birdhouses erected for purple martins. Some people assist martins by destroying sparrow and starling nests as they are built, and others resort to shooting or trapping these interloping species.

The purple martin, regarded by some as the premier backyard dweller in North America, actually has been nesting in large colonies only a short time. People have provided martins with an abundance of new nesting sites; they have also provided pest species that compete for those nesting sites. The purple martin thus presents an opportunity for evolutionary study: over time, we can observe whether these birds adapt further to a colonial life style. □

Celestial Events

by Thomas D. Nicholson

The Moon The evening crescent moon in May should be seen by the 6th or 7th, passing beneath Pollux and Castor (the "twin" stars of Gemini) on the 8th. First-quarter moon is on the 10th, full moon on the 18th, and last-quarter (the morning moon) on the 26th. In June, the evening crescent will appear on the 5th in Cancer, move into Leo on the 6th, and pass very close to Regulus on the 7th. By June 9, the moon is at first-quarter, and will be full on June 17, in Sagittarius very near the winter solstice. The full moon of the 17th is the lowest full moon of the year, in the sense that it spends the least time and travels on the shortest arc in crossing the sky from rising to setting. Perigee moon (nearest the earth) occurs on May 4 and June 1; apogee (farthest from the earth) occurs on May 17 and June 13.

Stars and Planets Mercury, Venus, Jupiter, Saturn, Uranus (after May 18), Neptune (after June 14), and Pluto are in the evening sky; Mars, Uranus (until May 18), and Neptune (until June 14) are morning stars. Jupiter and Saturn are easily visible from dusk until they set after midnight. During the early evening, look high in the south; the brighter of the two is Jupiter (brighter than any other object these nights except the moon). Saturn is just slightly to Jupiter's left. Farther still to the left, the bright star is Spica, in Virgo. Watch carefully during May and June, and you will see Jupiter part slowly from Saturn as both move away from Spica. In June, Jupiter will begin closing the gap with Saturn as both planets, reversing their motion through the stars, move nearer to Spica. At the end of July, Jupiter will pass Saturn in the third and last of the "triple conjunction" series, which has been taking place since January.

The only other planet in relatively good position this month is Mercury, going through a favorable evening elongation. From mid-May until early June, Mercury will be low in the west about three-quarters of an hour past sundown, looking much like a very bright star below the twin stars of Gemini (Pollux and Castor). You may begin to see Venus, much brighter than Mercury, but lower, in the last week of May, setting in the sunset glow. If so, look above it for Mercury.

The sun moves from the constellation Aries into Taurus in mid-May, and Mercury, Venus, and Mars move along with it through these groups of stars, Mercury ending up in Gemini in late May and Venus in Gemini in early June. Jupiter and Saturn are in Virgo, Uranus is in Libra, Neptune in Ophiuchus, and Pluto near the border between Boötes and Virgo.

May 3–4: The Eta Aquarid meteor shower (up to twenty often bright meteors per hour) reaches maximum on the morning of the 4th.

May 8: The two bright stars above the crescent moon tonight are Pollux and Castor.

May 10–11: The first-quarter moon is near Regulus in Leo on the night of the 10th. It passes the star during the day on the 11th and appears east of it (to its left) that evening.

May 13–14: The moon, now in its waxing gibbous phase, passes Jupiter and Saturn tonight. It moves closest to Jupiter at about 10:00 P.M., EST, closest to Saturn at about 4:00 A.M. on the 14th. It will be readily visible as it moves between the two planets during the intervening hours.

May 15: The moon is near Spica, the bright star of Virgo, tonight, well to the left (east) of Jupiter and Saturn.

May 19: The bright star tonight near the moon, just one day past full, is Antares, in Scorpius.

May 26: Mercury is at maximum easterly elongation, its greatest distance to the left (east) of the sun. This places the planet in its best position to be seen as an evening star, since it remains above the horizon after sundown. Not all elongations are equally favorable for viewing the planet, but this is a good one since Mercury is still fairly high as the sun goes down, remaining above the horizon into the late twilight, when the western sky is dark enough to see it. Until the end of May, you can find the planet low in the west, below the stars Pollux and Castor.

May 28: Jupiter ends its retrograde motion and resumes its direct (easterly) movement among the stars. It now begins to move back toward Saturn, having last passed that planet in February.

June 3: The new crescent moon may be too slim and dim to see tonight, but look carefully in the west about half an hour after sundown. If you can find Venus, look below it, and the crescent should be there.

June 5: Saturn is stationary among the stars today, joining Jupiter in resuming its normal easterly motion (to the left, relative to the stars around it). In another week or so, Jupiter and Saturn will be noticeably moving closer to Spica (the bright star to their left).

June 9: Mercury is stationary and begins to move westerly (retrograde). It is in conjunction with Venus today.

June 9–10: The moon moves past Jupiter and Saturn during the morning of the 10th. From one night to the next, it will shift from the right to the left of the two planets.

The Earliest Traces of a Conservation Conscience

The preservation of natural resources proves to be an ancient concept

by Robert M. Alison

Twenty-six years after my coronation, I declared that the following animals were not to be killed: parrots, mynas, the aruna, ruddy geese, wild geese, the nandimukha, cranes, bats, queen ants, terrapins, boneless fish [prawns] . . . tortoises and porcupines, squirrels, twelve-antler stags . . . household animals and vermin, rhinoceroses, white pigeons, domestic pigeons and all quadrupeds which are not useful or edible. . . . Forests must not be burned.

Asoka, emperor of India, 274–232 B.C.

A great many North Americans would probably be surprised to learn that the conservation of natural resources is a subject that has plagued almost every civilization that has ever existed. The earliest attempts to combat the sometimes overly exuberant use of resources by humans date to at least the Egyptian period. Of course, certain problems have been specific to particular societies, and thus remedial actions, in the form of laws, have varied widely in degree and target. Nonetheless, examination of the legal prohibitions set forth by leaders of the more than twenty civilizations that have appeared on the face of this planet, some of which have long since vanished, reveals consistent attempts by lawmakers to control the rates of natural resource consumption and environmental degradation.

Some of the earliest recorded instances were no more than crudely worded statements of penalties to be imposed in the event that a designated marshland was destroyed or that trees in a certain area were cut down by unauthorized individuals. With increasing technological advancement came ever more fantastic embellishments, both in wording and sphere of effect.

A few themes have consistently dominated the attention of conservationists throughout the millenniums. Notable among these has been a more or less universal infatuation with the concept of wilderness preserves—land set aside by a government for the perpetuation of its resident flora and fauna. One of the first of these was constructed by Ikhnaton, king of Egypt, more than three thousand years ago. Others were established, on independent initiative, by the Assyrian kings, beginning with Tiglathpileser I, in the eleventh century B.C.; the Greek city-states from the period of Xenophon (ca. 360 B.C.) onward; the Indian rulers beginning with Asoka; the Chinese from the reign of Hsiao-hsuan (ca. 100 B.C.); the Romans from A.D. 23; the Mongol Kublai Khan; the Aztec Montezuma; the Inca Pachacuti, and many more.

Wildlife preservation, in the form of laws regulating the taking of wild animals, has been an equally persistent aspiration. The earliest relevant laws seem to have been spawned by the Middle Kingdom pharaohs, who issued the first hunting licenses in order to regulate the activities of waterfowl hunters in congested marshes. Restrictions on the hunting of animals were put into effect in each of the known civilizations, including many limitations that had the effect of affording wild animals better treatment than that enjoyed by human residents.

Protection of vegetation, particularly trees, has been another consistent endeavor. Indeed, the earliest law protecting trees was formulated about 1900 B.C. by the authors of the Sumero-Babylonian Lipit-Ishtar law code, which prescribed a penalty of "one-half mina of silver" for cutting down a tree.

Perhaps nowhere has the so-called environmental conscience, as a distinct component of the global conservation movement, been so deeply rooted as in England. Consequently, a perusal of the numerous English laws enacted over the centuries affords a unique opportunity to appreciate the natural progression of concern, including relative priorities, that has occurred there.

That is not to say that events in England have mirrored those elsewhere. But they reflect an unmistakable regularity of theme.

One of the most remarkably persistent features of the colorful and well-recorded history of England has been a steady, almost fanatic dedication to the principles of natural-resource conservation. Although the most determined advocates were those sovereigns who had special interests in the environment, virtually no English king or queen after Alfred (ca. A.D. 892) was able to resist creating at least one outstanding contribution to the conservation cause.

Owing to the successful Roman invasion of England in the first century A.D., a substantial influence of Roman law upon subsequent English law is evident to this day. Indeed, it was not until the reign of Ethelbert (ca. 600) that major deviation from Roman doctrine was generated. The earliest English conservation law of which any record remains was formulated by Ine (ca. 700), whose Wessex law code stipulated that forests could not be

Pheasant

The Bettmann Archive

burned, meting out penalties for any infraction and further prohibiting the cutting down of any tree "big enough to shelter thirty swine."

At the beginning of the seventh century, England's forests were dominant features of the landscape, with great woodlots such as those of Beverley, Dean, Morfe, Kinver, Wyre, Rockingham, Selwood, and Sherwood. Marshlands were also a common integrant, particularly those of Romney and Pevensy, as well as the entire Thames estuary itself. At that time, central England comprised an almost continuous tract of bogs and fens, traversed by many streams and studded with wooded islands. In the following two centuries, however, the population increased, and with that, resources began to be developed to the point where many marshes were drained and woodland areas were reduced in size. Rivers were diverted, dams constructed, and livestock permitted to pasture virtually anywhere. As more acreage came under the plow, the ranges of many species of wild flora and fauna were greatly reduced. Such was the situation that faced the Norman conquerors in 1066.

In this period, the word *forest* had a special legal meaning. It applied to certain wide districts scattered throughout the realm, within which the king established an exclusive right to hunt and to manage the habitat accordingly. A court judged violations of strict forest laws, handing down extremely cruel penalties. These laws were enforced by the chief forester, aided by a number of foresters and wardens, each of whom had authority in a specified bailiwick.

The conservation contributions of the first two Norman kings were vastly overshadowed by those of Henry II's "assize of the forest" (1184), which placed strict controls over the activities of commoners, mostly within the royal forest holdings; established protection for game animals; and regulated trapping. He also prohibited night hunting, an activity first condemned by the Greeks at the time of Xenophon.

Prior to the reign of Henry III, conservation had been almost exclusively a royal concern. In November 1217, however, that monarch produced the "charter of the forest," which for the first time forced owners of private forests to reforest large tracts of land that had been denuded for livestock pasturage: "Woods may not be sold nor wasted by them that hold them."

National Portrait Gallery, London

Edward IV

Whereas the Norman and Angevin kings of England legislated by means of charters and assizes, from the time of Edward I (1272–1307), English laws were created in the form of statutes—acts of Parliament. The last of the English charters was the Magna Charta (1215) signed by the beleaguered John I, which devoted two of its sixty-three sections to environment-related topics. Section 44 abolished the forest courts while section 47 provided for a reforestation program in all royal forests and along all river banks.

The first act on the subject of conservation, formulated during the time of Edward I, protected salmon "from the Nativity of Our Lady unto Saint Martin's Day." The same act also abolished the penalty of death or dismemberment for the killing of a deer.

Edward III established the first trapping season in 1337 by prohibiting the purchase of furs after the Feast of Saint Michael.

Under Richard II, the hunting of wild animals became restricted to certain classes of people, excluding all "manner of Artificer, Labourer, and other layman [of a specified land holding] . . . Priest, or other Clerk."

Henry VI generated two conservation statutes. In 1423, to protect the "Brood and Fry of Fish," he prohibited the setting of nets in the rivers of England. Four years later, concerned about the rapid deterioration of coastal marshes and sea banks, he enacted legislation to remedy the "Hurt that within short Time will happen."

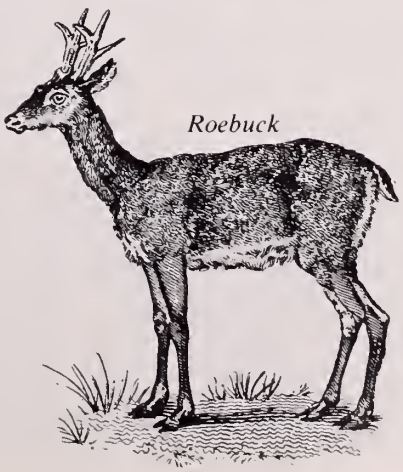
Edward IV prohibited the private possession of swans by anyone whose lands were valued at less than five marks yearly, thus officially making that bird a symbol of aristocracy.

Beginning in 1495, Henry VII churned out a series of statutes prohibiting the capture or killing of "feasants and partridge" except under the authority of a license issued by the landowner; the taking of hawk or swan eggs from the wild; the possession of certain species of hawks; and the use of nets or other contrivances for capturing deer.

The inexhaustible Henry VIII was a prolific author of statutes relating to environmental protection and hunting. He was an avid hunter and naturalist, a fact that is reflected in the wording employed in several of his statutes. His first enactment prohibited the hunting of hares on snow-covered ground, since "Hare . . . which

Game is now decayed, and almost utterly destroyed, for that divers Persons in divers Parts of this Realm, by reason of the tracing in Snow, have killed and destroyed, and daily to kill and destroy the same Hares. . . ." Shortly thereafter, legislation was prepared that protected certain of the most notable of the Thames River marshes from flooding. In 1533, Henry established the first English waterfowl season. Entitled "An act to avoid the destroying of Wild-fowl," the legislation created a closed season from May 1 to August 31, violation of which would be penalized by one year's imprisonment. Waterfowl eggs were likewise protected from March 1 until June 30. Six years later, severe penalties were set forth for anyone who violated strict regulations relative to the taking or possession of any "Faucon, Goshawke, or Laneret," or their eggs.

Henry VIII hated crows and ravens. During his reign, unusually severe anticrow laws were created, specifying that all persons in England "shall hereafter do and cause to be done as much as in him . . . reasonably shall be or may be, to kill and utterly destroy all manner of Crows, Rookes and Chouges," establishing a generous bounty, and forming a committee whose task it would be to supervise the eradication program.



Edward VI and Elizabeth I devoted their energy to the common practice of poaching, an activity that had plagued landowners for centuries. Elizabeth went on to prohibit the use of nets in taking pheasants or partridge and to establish a closed season on these birds, because "the Game of Pheasants and Partridges is within these few Years in Manner utterly decayed and destroyed in all Parts of this Realm."

During the next 200 years, a steady stream of statutes came into being; virtually all of them addressed the increasingly stinging issue of wildlife management, or rather, game management. Statutes were created relative to falconry (James I); deer poaching (Charles II); "preservation of game," including the prohibition of sale (Anne); "deer stealers" and a new schedule of fines for game-related offenses (William and Mary); collection of fines levied for game offenses (George II); closed seasons for red grouse, partridge, pheasant, and black grouse in Scotland and the preservation of pigeons (George III).

Partridge

The Bettmann Archive

In 1770, George III regulated shooting periods pertaining to game birds, restricting hunting hours to from one-half hour before sunrise to one-half hour after sunset—violators earned a penalty of six months imprisonment and a public whipping. The same king established a period of "six calendar months" during which any person who had bought or sold game could be prosecuted.

The problem of game poaching preoccupied George IV. The preamble to the statute that he formulated on the subject began: "Whereas the Practice of going out by night for the purpose of destroying game has very much increased of late years, and has in very many instances led to the commission of murder. . . ." It was decided that an appropriate penalty for violation would be three years hard labor or, alternatively, fourteen years in North America.

On October 5, 1831, William IV produced a statute that summarized and clarified the game legislation that had been devised during the previous five centuries, including novelties never before put into effect. In its forty-eight sections, the statute dealt with such things as hunting on Sundays, the use of poison, dealing in game, hunting licenses, court procedure, trespass in search of game, and ownership of game. In common with virtually all its predecessors, it did not mention habitat management, habitat preservation, or some of the other issues that in recent times have been grouped under the broad heading of conservation.

With Victoria came the zenith of conservation consciousness in England; in no other single reign were so many statutes on that subject created. From 1860 to 1892, eight distinct acts of Parliament dealing with game licenses, poaching prevention, sea bird preservation, wild bird protection (two acts), wildfowl protection, ground game, and hares were put into effect.

But as England stepped into the twentieth century, despite hundreds of statutes and ordinances, major components of the sphere of conservation remained unaddressed. Whereas there were laws relating to seventy-one species of birds (not including hawks), several species of mammals, and a few species of fish, not yet noticed was the plight of nongame animals, including most fish and all reptiles and amphibians. There were laws relating to trees, which were marketable,

but not to other vegetation, for which there was no market. Habitats, aquatic or otherwise, were destroyed with impunity. Nobody had given any thought whatsoever to environmental contamination. The question of humaneness in hunting, fishing, and trapping had not been considered. All these issues would crop up in the twentieth century.

The situation has always been the same. Caught up in immediate problems, societies could rarely afford the luxury of insight into future dilemmas and responded to crises in much the same manner as modern legislators. They reacted to obvious declines in animal populations by reducing the mortality of a target species, but not by providing places in the environment for the increased population to live and thrive. Since nobody had ever complained about plant rarity or floral extinction, this subject was ignored.

In the latter half of the twentieth century, most developed countries have accomplished a degree of conservation legislation appropriate to their degree of affluence. In the Western world, we have reached a level of human comfort hitherto unavailable to masses of people, and as a result, our lawmakers have been able to devote their time to such subjects as conservation, which might, at other times and in other places, have been left unaddressed.

Who knows the extent to which the conservation movement will influence future Western society? We have already seen that the presence of a tiny fish in an American river can halt the construction of a multimillion dollar power facility. In England, there is pressure for the enactment of a law requiring that the killing of shrimp and lobsters be made more humane. Environmental impact statements are becoming commonplace requirements.

Examination of the laws of the various civilizations that have existed to date reveals that conservation enthusiasm emerges early in the evolution of a particular society. But its refined incorporation into the actual behavior of citizens, in terms of positive effect, is restricted to the advanced stages of the society, since only then can it afford the luxury of concern.

A Nonconforming Supernova

Cassiopeia A has not behaved the way supernovae of its type are supposed to

by Stephen P. Maran

Cassiopeia A, an expanding nebula from a seventeenth-century supernova explosion in the Cassiopeia constellation, is the youngest supernova remnant in our galaxy. Unlike other supernovae of historical times, however, it was not readily visible from the earth when it exploded, an unusual circumstance that has prompted much theorizing. There are two categories of supernovae: type I, produced by relatively low-mass stars; and type II, produced by high-mass stars. According to accepted ideas about type II supernovae, the category to which the Cas A explosion is assigned, either a neutron star or a black hole should have formed in the remnant. Neither, however, has been found, and some astronomers believe that the star that produced Cas A must have been totally disrupted by the explosion.

Cas A is a powerful radio source, a fact that caused its discovery in 1948 with a rather primitive radio telescope at Cambridge University in England. In 1951, more advanced equipment determined the precise location of the source, enabling astronomers in California to pinpoint it on photographs made with the 200-inch telescope at Mount Palomar. In the photographs of the location of the radio source, they found a very dim nebula composed of many small gaseous structures. These have since been classified into two groups termed knots and flocculi, respectively. Subsequent study also shows that the two groups of structures are moving out from the center of Cas A at different speeds, and that they also differ markedly in chemical composition. The knots move at the enormous speed of 3,700 miles per second; the flocculi move at only one-twentieth of that velocity. The knots are going so fast that they can actually be seen to move on telescopic photographs made just a few years apart. When the motions of the knots are traced backward on the photographs, you can deduce when and where the supernova explosion that produced them must have occurred. Estimates for the date range from A.D. 1657 to 1671. Spectra also show the chemical differences between the two groups. The flocculi have abnormally high ratios of nitrogen to hydrogen. By contrast, the spectra of the knots show no hydrogen or nitrogen, lack prominent emissions of iron, and reveal the presence of much oxygen.

If astronomers had reported seeing the Cas A supernova when it exploded, we would, of course, know its correct date, but they did not. Calculations based on the properties of other supernovae indicate that the Cas A event should have been easily visible. Estimates of its brightness differ, but range from an apparent magnitude of −2.5, brighter than any star of the night sky, to magnitude +2, the brightness of the North Star. At any magnitude in this range, the supernova would have been visible without difficulty to the unaided eye. Another supernova, called Tycho's star, was seen in the constellation Cassiopeia

in 1572, but no "new star" was found in that constellation during the period from 1657 to 1671 nor, indeed, has one been found at any time since.

That Cas A exploded without a "new star" being seen presents an enigma that has interested many scientists. According to one often discussed theory—proposed long ago by another scientist, but revived and revised recently by Roger Chevalier, an astrophysicist at Kitt Peak National Observatory in Tucson, Arizona—the exploding star was much smaller than usual for a type II supernova because it somehow shed its voluminous outer layer *before* the explosion occurred. This would make the supernova about 7 magnitudes dimmer than previously calculated, with an apparent magnitude of +4.5 at the brightest. A star of that magnitude is visible although not conspicuous to the naked eye and thus could have been overlooked.

A second explanation was advanced by Iosif Shklovsky, a world authority on supernovae at the Space Research Institute in Moscow. He believes (as I do) that the light from a type II supernova is not produced just by the explosion. Instead, the supernova luminosity may be largely powered by energy from a newborn pulsar formed when the star collapses and explodes. Thus, the size of the presupernova star would be less important in determining the supernova brightness than the properties of the new pulsar.

A pulsar is a highly magnetized, rapidly spinning neutron star, about

Better Than Jogging

NordicTrack

Jarless Total Body Cardiovascular Exerciser Duplicates X-C Skiing for the Best Motion in Fitness

This revolutionary new exerciser duplicates the smooth, rhythmic, total body motion of X-C skiing for the most effective cardiovascular exercise obtainable. Uniformly exercises more muscles than any other exercise device. Makes high heart rates easy to obtain and keeps more muscles in tone. Also highly effective for weight reduction.

Completely jarless natural motion does not cause joint and back problems as in jogging or running. Arm and leg resistances are separately adjustable for maximum effectiveness. The NordicTrack uses no motors and folds compactly for convenience. Used in homes, businesses, and institutions. Our customers include Xerox Corporation, US Army, Penn State U and the YMCA.

QUESTARS ARE FOR LOVERS OF FINE INSTRUMENTS

Questar's inventor, who loved fine instruments, designed Questar for himself. First there was a set of optics so fine that no amount of money, time, or human effort could improve upon it. Second, believing that a telescope's use should not be a difficult physical chore, he made it easily portable and small enough to be used on a table, where an observer could sit in a relaxed position. Third, accessories were built in, with fingertip controls within easy reach. Fourth, the mechanical design permitted polar equatorial positioning in a moment and without the need of a separate tripod. Fifth, for versatility in the field of nature study he introduced the ability to focus as close as ten feet, which no other telescope in the world could do. Sixth, he made the design photovisual with the ability to record on film whatever these superior optics would present to the eye. And finally he achieved the rugged construction that eliminated the vibration and aggravating oscillations so familiar to those using long-tubed conventional telescopes.

Let us tell you more about Lawrence Braymer's remarkable invention based on an optical system by Maksutov, which was the first break-through in telescope design in 200 years. Send for our booklet in color, describing Questar, the world's finest, most versatile telescope. $2, please, for mailing costs.

50 percent more massive than the sun, yet no larger than fifteen miles in diameter. In the immediate aftermath of its birth, a pulsar may shed energy at a fantastic rate, sufficient to propel and illuminate the surrounding nebula of the supernova. From the fact that no bright star was seen when Cas A exploded, Shklovsky deduced that no pulsar formed. If this conclusion is correct, the possibility remains that a so-called bare neutron star—one lacking the high magnetic field and fast spin of a pulsar—was formed. In that case, the supernova *would* be dim, but the bare neutron star, starting with an initial surface temperature of millions of degrees Celsius and cooling very slowly over the centuries, would still be observable today as a compact X-ray source at the center of Cas A.

Since no compact X-ray source exists in Cas A, Shklovsky concluded that not even a bare neutron star was left from the supernova. This position was recently reinforced by an X-ray image of Cas A, made with unprecedented sensitivity by the *Einstein* satellite, which confirms that there is no hint of a compact X-ray source at the center of Cas A. This leaves two likely possibilities concerning the Cas A explosion: either the presupernova was totally disrupted or the core of the presupernova collapsed to form a black hole.

Since there is no sure way of directly observing a black hole, we have to resort to indirect evidence that may bear on the question of whether a black hole formed in the supernova. In particular, the chemical composition of the knots may be relevant.

Nuclear reactions inside a star convert the gas there, which consists mostly of hydrogen and helium, to successively heavier elements. By the time a massive star has reached the developmental stage of a type II supernova, its central core should consist mostly of iron. The high speeds of the outward-flying knots in Cas A indicate that they must be fragments of the exploded star. Thus, if the core was disrupted along with any overlying layers, the knots should contain notable amounts of iron. As mentioned previously, however, the spectra of the knots lack the strong emissions of iron that would then be expected. Because of this circumstance, Shklovsky decided that the core of the presupernova star did not shatter and that since it did not form a neutron star, it must have become a black hole. Although this argument seems logical, it has not been generally accepted by astronomers. Some, for example, believe that the composition of the knots can be accounted for by nuclear transmutations during the supernova explosion itself.

I don't know how bright the supernova would have been if a black hole had formed, as theorized by Shklovsky. However, Chevalier's proposal that the supernova explosion that produced Cas A was smaller than usual at least predicts the supernova might have been visible to the naked eye as a dim star.

An astronomer active at the time of the explosion and therefore in a position to record it was John Flamsteed, England's first astronomer royal. He systematically tabulated the stars visible to the naked eye during the latter part of the seventeenth century and issued a catalog of them. Even today, many stars continue to be known by their "Flamsteed numbers," as assigned in his catalog. On August 16, 1680, Flamsteed observed what he later described as a sixth-magnitude star that he named 3 Cassiopeiae. There is no indication that he believed the object to be at all different from the many other stars that he was surveying. By means of a sextant, he determined the angular separations of the object from each of two bright stars: Scheat, in the constellation Pegasus, and Algol, the famous Demon star in Perseus. From these measurements, he later calculated the position of 3 Cassiopeiae.

As far as is known, neither Flamsteed nor anyone else ever saw 3 Cassiopeiae again. There is no star at the position he posited, so at various times astronomy historians have concluded that Flamsteed's August 1680 observations were erroneous. But three scholars within the past two years have pointed out independently that Flamsteed's derived position for 3 Cassiopeiae is very near the deduced expansion center of the knots in Cas A, suggesting the possibility that the dim star he observed may have been the supernova. In that case, the supernova would have exploded in 1680 rather than in the deduced 1657 to 1671 period. This discrepancy is not surprising, given the uncertainties in measuring the motions of the Cas A knots. In addition, there is the possibility that the expansion has slowed down since the explosion occurred, which would lead us to deduce an

erroneously early date for the supernova.

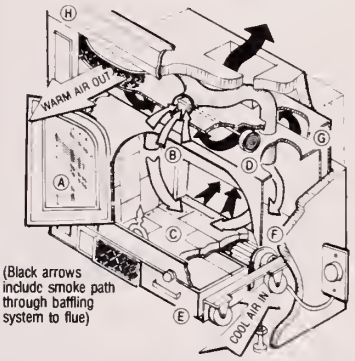
An analysis by one of the three scholars mentioned above convinced him that 3 Cassiopeiae was in fact the supernova. Another of the three, however, a specialist on Cas A at the David Dunlap Observatory in Toronto, reached the opposite conclusion. He thinks there probably never was a 3 Cassiopeiae. Instead, he believes that Flamsteed goofed and measured the arc from Scheat to a fifth-magnitude star and mistakenly measured the arc from Algol to a different, seventh-magnitude star, which he confused with the fifth-magnitude object. Thus, in mistaking one star for another, Flamsteed would have derived his published position for 3 Cassiopeiae from the two sextant measurements. This second interpretation implies that Flamsteed in fact made a double blunder, confusing the two stars with each other despite their different brightnesses and different positions. Nevertheless, there is no way today to tell whether Flamsteed's 3 Cassiopeiae was the supernova or whether his measurements were incorrect.

Since the interpretation of Flamsteed's records is ambiguous, we can only rely on modern observations to investigate the nature of the exploding star. They give us some useful hints about how the star evolved before the explosion, but nothing definitive about the event itself. The astronomer who has done the most comprehensive job of putting the observational data together and explaining what they mean is Susan Lamb of the University of Illinois (Urbana-Champaign). An expert on the evolution of massive stars, Lamb has deduced that the Cas A presupernova underwent *two* intervals of heavy loss of mass before the explosion occurred. Her reasoning goes like this: The high speeds of the knot structures prove that they were ejected in the explosion itself, while the lower velocities of the flocculi structures indicate that they were shed at least 10,000 years before the explosion (a fact already known). But the strange composition of the flocculi, with their heavy ratio of nitrogen to hydrogen, means that they did not come from the surface of a normal star since no stars have been found with such a heavy nitrogen concentration. Computations show, however, that such concentrations do form unseen, deep inside massive stars in the young blue supergiant stage. As the supergiant converts hydrogen to helium in the nuclear furnace of its core, it increases the ratio of nitrogen to hydrogen simply by diminishing the latter. A powerful stellar wind, acting over many hundreds of thousands of years, can blow off most or all of the unburned hydrogen layer that surrounds the zone of enhanced nitrogen. (Winds of sufficient power have been observed in young blue supergiants by the *Copernicus* and *International Ultraviolet Explorer* satellites.) According to Lamb's theory, this occurred a very long time ago, giving the windblown unburned hydrogen layer time to disperse in space beyond the possibility of recognition. Then, only 10,000 or so years ago, as the aging star approached its end, the wind picked up again, blowing off the nitrogen-enhanced material to form the flocculi. Heavy winds of the kind required by Lamb's hypothesis have been found in older red supergiant stars. Finally, about 300 to 325 years ago, the theory goes, the by then much smaller star exploded, creating the knots of Cas A.

Lamb's theory is consistent with Chevalier's idea that the supernova was dim because the exploding star was unusually small. The theory also doesn't seem to contradict Shklovsky's deduction that a black hole formed, although Lamb told me that she believes the presupernova star was wholly disrupted. Can we at least conclude that either there is a black hole in Cas A or that no condensed object was left by the explosion? Even on this question, the jury is still out. The possibility exists that some neutron-star-like objects are formed of subatomic particles called quarks, thought by physicists to be the ultimate building blocks of matter. Such a tiny neutron-star-like object, or quark star, would cool more rapidly than a neutron star and would thus not show up in the *Einstein* satellite survey for small hot spots in Cas A.

Advances in observational technology may ultimately make it possible for astronomers to determine what, if anything, still lurks within Cas A. Nevertheless, we will never know with certainty whether anyone actually saw the supernova.

Stephen P. Maran is a senior staff scientist in the Laboratory for Astronomy and Solar Physics at NASA's Goddard Space Flight Center in Greenbelt, Maryland.



The Shelburne Fireplace-Stove

Its graceful design is timeless, its engineering as new as tomorrow.

Those crackling flames can lift your spirits, but your open fireplace actually *wastes* more heat than it delivers. Perhaps you've discovered that tubular grates, glass doors and ordinary fireplace inserts offer only a partial solution at best. Yet a black metal woodstove on your hearth would be an affront to your room decor.

Efficiency on wheels

The Shelburne can transform your fireplace into a super-efficient heat producer without compromising the visual and soul-warming pleasures it provides. You enjoy a visible fire behind safe Corning Pyroceram glass. Downdraft combustion, 2000°F space-capsule insulation and a 40" baffle system help account for its amazing performance. And the Shelburne *rolls out* on your hearth for easy chimney cleaning.

(Black arrows include smoke path through baffling system to flue)

(A) Doors may be opened to view the fire (B) Air is preheated as it enters downdraft and secondary air tubes (C) Firebrick-lined ¼" steel firebox (D) Automatic thermostat (E) Pull-out ash pan (F) Fan with speed control (G) 40" baffling system (H) Flanges in choice of 3 widths permit installation in over 80% of all fireplaces.

WILDERNESS TRAILS IDAHO. Backpacking, Ski-touring, and Bicycle-touring. Come adventure and learn with us. Trips for all abilities, everything provided. We have thirteen years experience and guide only in Idaho. Write: P.O. 9252 M, Moscow, Idaho 83843 (208) 882-1955

RATES AND STYLE INFORMATION

$1.75 per word; 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired. Occasionally, slight editing is required for clarity. Thank you!

Frozen Fish

Frozen fish is definitely déclassé in the world of *haute cuisine*. But to the American Museum of Natural History, one frozen fish is so desirable that the Museum has been going to great lengths to obtain it.

For six months, Guido Dingerkus of the Ichthyology Department has been trying to arrange the delivery of a frozen coelacanth from Zimbabwe to New York. Unfortunately, shipping a 120-pound frozen fish halfway around the world is not like shipping fish sticks from Cape Cod to Des Moines. Dingerkus has run into a long series of problems and delays that threaten to prevent the fish from ever reaching the Museum.

The coelacanth is often called a living fossil because until recently it was believed to have been extinct for 30 million years. It is a fascinating animal for several reasons. Some zoologists think it is closely related to the primitive, lobe-finned group of fishes that gave rise to the first land vertebrates, the amphibians, which eventually led to *Homo sapiens*. By studying the frozen fish, it may be possible to learn more about the transition of vertebrate life from water to land.

The coelacanth in question was caught in June of 1980 off the Comoros Islands (near Madagascar), the only area where coelacanths are found. The local Comoros fishermen know that these strange, lobe-finned fish will sometimes fetch high rewards if preserved. (Before the living coelacanth was discovered by scientists, the islanders had been catching and eating them, as well as using their skin for patching bicycle tires.) Someone apparently thought that a frozen coelacanth would fetch more money than a preserved one and stored it in a meat locker. It was put up for sale at $2,000 (or $17 per pound — not bad when you consider the price of lobster tails), but after several months with no buyers, the discouraged entrepreneur donated the fish to the National Museum of Zimbabwe.

Only two frozen coelacanths have entered the United States. Both were caught by an expedition of the California Academy of Sciences led by John McCosker, who tried unsuccessfully to capture a live coelacanth to exhibit at Steinhart Aquarium in San Francisco. Frozen coelacanths are superior to preserved ones because their biochemicals, chromosomes, and cell structures remain intact.

When Dingerkus learned of the frozen coelacanth in Zimbabwe, he contacted the director of the national museum there. The director told him that his museum only wanted a cast of the fish; the American Museum could have the original. Dingerkus was delighted and promised to send him a first-rate cast when the fish came in.

Gary Littman of Sloan-Kettering Institute, who had long wanted to study the blood and muscle proteins of the coelacanth, volunteered to pay all shipping expenses. Furthermore, an airline, hoping for some publicity, agreed to ship the fish free of charge. Everything seemed settled.

But months passed and the fish never arrived. After numerous telephone calls, Littman and Dingerkus found out that the airline people had changed their mind: not only did they refuse to deliver the fish for free, they were not going to deliver it at any price. No other airline, it turned out,

Illicit Antiquities

Visions of Antiquity: Licit and Illicit, a series of films followed by discussions, will be presented in the Auditorium on three Mondays—May 4, 11, and 18—at 7:00 P.M. *The Plunderers: Treasure Trail* examines the illegal digging and plundering of ancient tombs by poor Turkish farmers. *The Plunderers: The Hot Pot* investigates the Metropolitan Museum of Art's controversial, million-dollar purchase of the Euphronios vase, which was probably stolen from a tomb, and documents the destruction of Etruscan and Egyptian antiquities by tomb robbers. *The Royal Archives of Ebla* shows the recent excavations in Syria that have unearthed 17,000 clay tablets. The tablets, which are still in the early stages of translation, seem to be related to biblical texts. Tickets for the series are $18 ($12 for members); call the Education Department for more information.

Forever Young

In his new documentary, *Forever Young*, Academy Award-winning director Robin Lehman talks to elderly people

would guarantee delivery of a fully frozen fish, and a rotten coelacanth is far worse than no coelacanth at all.

"It was back to square one," says Dingerkus. "Here we had this frozen fish of great scientific value, and no way to get it." After several more weeks of haggling, he finally convinced the airline to transport the fish for its usual shipping costs—about $5,000. The fish will be packed in 120 pounds of dry ice and crated. If all goes well, it might be in the Museum's freezer next month, sharing quarters with a frozen rhinoceros, a pile of frozen sharks, and other frozen animals.

The thawing of the coelacanth, Dingerkus explained, will be a major scientific event. "A fair number of scientists will be flying in from different parts of the country to work on the fish. As it thaws from the outside, we will begin dissecting when it is semifrozen, semisquishy. It is more critical to get certain things out fast. Everyone will get a piece."

But with shipping difficulties continuing, Dingerkus thinks this may all be wishful thinking. "I'll only believe we've got it when I see it sitting in our freezer."

If the fish ever arrives, it will be the Museum's third coelacanth. In 1961, the first coelacanth sent to North America arrived at the Museum in a large coffin. The local Comoros fishermen had carried it to a hospital, where one of the surgeons recognized it and emptied his hospital of Formalin (a solution similar to embalming fluid) to preserve it.

The fish was finally dissected by a team of Museum scientists in 1972. To everyone's astonishment, out popped five fully-formed young, immediately settling the question of whether the coelacanth lays eggs or bears live offspring. The American Museum sent one of the young to the Paris Museum of Natural History and received an adult male in return, thus rounding out the collection.

This pregnant female was, not surprisingly, the heaviest coelacanth ever caught. The frozen fish that the Museum is trying to acquire is almost as heavy and thus may also be pregnant. Says Dingerkus, "We're secretly keeping our fingers crossed."

Douglas J. Preston

and dispels many of the fears and prejudices associated with growing old. Sponsored by the Education Department, the free film will be shown on Sunday, May 3, at 2:00 P.M. in the Auditorium.

African Diaspora

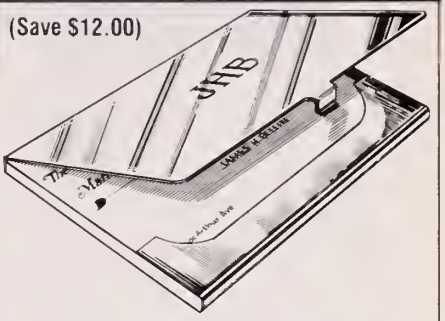
African Diaspora: Caribbean Expression, a series of films on African traditions that were brought to the New World, will be shown on two Wednesday evenings, May 20 and 27, at 7:00 P.M. in the Auditorium. The series, presented by the Education Department, will explore, in particular, African religious systems found in the New World, such as the condomble of Brazil and the voodoo of Haiti.

Traditional Voices

Versions of the Traditional, a series of poetry readings and songs sponsored by the Education Department and the Touchstone Center, includes two free programs in May. The first, on May 6, will present readings of the Nuer of Ethiopia; the second, on May 20, will be on Eskimo poetry.

From Russia with Love

On Sunday, May 10, the graduating class of the High School of the Performing Arts will present *Panorama of Dance,* featuring a variety of dance forms from Russian classics to contemporary American. The free dance concert, presented by the Education Department, will be given in the Auditorium at 2:00 P.M.



Museum Highlights

Every day in the Museum, free tours of selected exhibition halls are available for individuals, families, and groups of up to twenty people (although not for school or day-care groups). Check in at any Information Desk when you visit to find out about tours available on that day. For more information on personalized group tours, including some for non-English-speaking visitors, contact the Volunteer Office at (212) 873-1300, ext. 538.

For more information about programs, call the appropriate department: Membership Office (212) 873-1327; Education Department (212) 873-7507; Planetarium (212) 873-1300, ext. 389.

Mount St. Helens (p. 36)

Recently revised to include a description of the Mount St. Helens eruption, S.L. Harris's *Fire and Ice* (Seattle: Pacific Search Press, 1980) is a classic, semipopular account of the geology of the seventeen major Cascades volcanoes. Meant for the general scientific audience, C.L. Rosenfeld's "Observations on the Mount St. Helens Eruption" (*American Scientist,* vol. 68, no. 5, pp. 494–509) is a clear description of the recent eruptions of Mount St. Helens. "The Eruptions of Mount St. Helens," by R. Decker and B. Decker (*Scientific American,* March 1981, pp. 68–80) covers the mountain's history, the effects of the recent eruptions, and the prospects for future volcanic activity. Less technical are R. Findley's "Mountain with a Death Wish," "In the Path of Destruction," and "The Day the Sky Fell" (*National Geographic,* January 1981, pp. 3–65), which cover the eruption and its consequences for the environment, the economy, and the geology of the area. Among the many picture books that have appeared on the eruption are *Volcano: The Eruption of Mount St. Helens* (Longview: Longview and Madrona Publishers, 1980); *Mt. St. Helens: Holocaust* (Lubbock: C.F. Boone Publishers, 1980); and *Mt. St. Helens—The Volcano Explodes!* (New York: SINO Publishing Co., 1980). For background reading, P. Francis's *Volcanoes* (New York: Penguin Books, 1976) is a lucid introduction to the history, structure, and formation of volcanoes.

Anglerfish (p. 50)

Using high-speed, light cinematography, D.B. Grobecker and T.W. Pietsch show that shallow-water anglerfish have one of the fastest vertebrate feeding mechanisms known. They describe the fish's rapid prey capture in "High-Speed Cinematographic Evidence for Ultrafast Feeding in Antennariid Anglerfishes" (*Science,* September 14, 1979, pp. 1161–62). In "The Compleat Angler: Aggressive Mimicry in an Antennariid Anglerfish" (*Science,* July 28, 1978, pp. 369–70), T.W. Pietsch and D.B. Grobecker describe how an anglerfish of the genus *Antennarius* conserves energy by using a bait that mimics a small fish to attract prey. A short article describing the anglerfish and its behavior, "Strange Animal Lures," by J.W. Atz (*Animal Kingdom,* July–August 1950, pp. 110–13) also discusses similar phenomena of mimicry in the alligator snapping turtle and the copperhead snake. W.G. Eberhard explains how a mature female bolas spider attracts prey with a volatile substance that mimics the female sex-attractant pheromone of a fall armyworm in "Aggressive Chemical Mimicry by a Bolas Spider" (*Science,* December 16, 1977, pp. 1173–75).

Dugongs (p. 54)

In 1888, tired of lecturing about things he had never seen, zoology professor A.C. Haddon left Dublin to research coral reefs and marine fauna in the Torres Strait, but soon became more interested in the people. Ten years later, Haddon returned to the Torres Strait as head of a Cambridge University expedition that conducted the first scientific interdisciplinary study of a primitive people. The results of this classic study, edited by Haddon, were published in six volumes, *Reports of the Cambridge Anthropological Expedition to the Torres Strait* (Cambridge: Cambridge University Press, 1901–35). Haddon also wrote a popular account of his research, *Headhunters: Black, White and Brown* (London: Methuen and Co., 1901). More recent material on Torres Strait Islanders can be found in *Sunda and Sahul,* a work on prehistoric societies in Southeast Asia, Melanesia, and Australia, edited by J. Allen, J. Golson, and R. Jones (London: Academic Press, 1977), that includes D.R. Harris's "Subsistence Strategies Across Torres Strait." Harris also looks at the relationships be-

tween island size and resource base, trade, and the development of socio-economic systems in "Foragers and Farmers in the Western Torres Strait Islands: An Historical Analysis of Economic, Demographic, and Spatial Differentiation" (*Social and Ecological Systems,* edited by P. Burnham and R.F. Ellen. London: Academic Press, 1979). The first European contacts with Torres Strait Islanders are the focus of D.R. Moore's *Islanders and Aborigines at Cape York* (Canberra: Australian Institute of Aboriginal Studies, 1979) and *The Journal of John Sweatman,* edited by J. Allen and P. Corris (Brisbane: University of Queensland Press, 1977). In "The Wind Caller" (*Natural History,* March 1977, pp. 10–16), B. Nietschmann recalls some of the experiences he and his family had while learning about the Islanders' knowledge of the environment. M. Lawrie's *Myths and Legends of Torres Strait* (Brisbane: University of Queensland Press, 1970) is a nicely illustrated collection of many old tales. Australian novelist I.L. Idriess wrote several books based on a rather loose interpretation of Torres Strait cultural history, such as *The Drums of Mer* (Sydney: Angus and Robertson, 1933) and *Wild White Man of Badu* (Sydney: Angus and Robertson, 1950). Literature on dugongs is slim, but has recently been increasing. A good, although dated, overview of dugong numbers and habitats can be found in G.C.L. Bertram and C.K.R. Bertram's "The Modern Sirenia: Their Distribution and Status" (*Biological Journal of the Linnaean Society,* vol. 5, no. 4, 1973, pp. 297–338), which includes a section on dugongs in the Torres Strait. Zoologist G. Heinsohn has been studying dugongs since 1969; some of the results of his research are summarized in "Sirens of Tropical Australia" (*Australian Natural History,* vol. 19, no. 4, 1978, p. 106–111). Heinsohn collaborated with P. Anderson on "The Status of the Dugong and Dugong Hunting in Australian Waters: A Survey of Local Perceptions" (*Biological Conservation,* vol. 13, 1978, pp. 13–26). Heinsohn, Anderson, and H. Marsh wrote "Australian Dugong," a good, illustrated review of habitats, behavior, and ecology (*Oceans,* May–June 1979, pp. 48–52). P. Anderson presents the results of his research at Shark Bay, Western Australia—one of the few places where dugongs are not hunted—in "Dugong Behavior: On Being a Marine Mammalian Grazer" (*The Biologist,* vol. 61, no. 4, 1980, pp. 113–44). R. Bustard's *Sea Turtles* (New York: Taplinger, 1972) includes some discussion of sea turtles in the Torres Strait.

Purple Martins (p. 64)

A complete guide to the purple martin meant primarily for the layman, R.B. Layton's *The Purple Martin* (Jackson: Nature Books Publishers, 1971) contains information on the martin's migration, what it eats, how it nests, and also gives hints on building a martin house. A classic work on purple martins is R.W. Allen and M.M. Nice's "A Study of the Breeding Biology of the Purple Martin" (*American Midland Naturalist,* vol. 47, no. 3, 1952, pp. 606–65). *The Nature Society News,* formerly the *Purple Martin News,* devotes most of its pages to purple martins. Published by the Nature Society, Purple Martin Junction, Griggsville, Illinois 62340, this newspaper regularly features a guide for new members entitled "How to Become a Purple Martin Landlord." Also published by this society is J.L. Wade's popular paperback, now in its seventh printing, *What You Should Know About the Purple Martin* (Griggsville: The Nature Society, 1979). R.F. Johnston and J.W. Hardy's "Behavior of the Purple Martin" (*Wilson Bulletin,* vol. 74, September 1962, pp. 243–62) is a detailed, descriptive account of reproductive, aggressive, and group behavior of purple martins.

Enter the world of Questers nature tours.

When you travel with Questers, you have the advantage of our knowledge of the travel world And our experience of the natural world We are travel professionals And our only tour program is Worldwide Nature Tours

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers rain forests, mountains, and tundra seashores, lakes, and swamps of the regions we explore. At the same time, we include the more usual attractions in touring—the cities, archaeological sites, and people

The current Directory of Worldwide Nature Tours describes 29 tours varying from 9 to 36 days and going to virtually every part of the world Included are The Amazon, Peru, Patagonia, Galapagos, Hawaii, Alaska, Death Valley, Everglades, Ladakh, Sri Lanka, Iceland, Scotland, Greece, Australia, and New Zealand Tour parties are small, the pace leisurely, and itineraries unusual

Beastly Rights

by Joseph Kastner

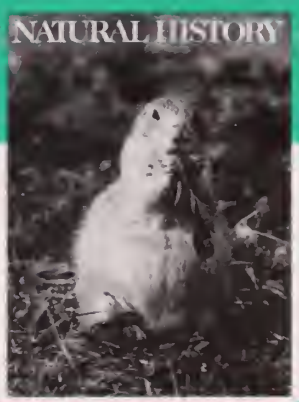
RECKONING WITH THE BEAST, by James Turner. *The Johns Hopkins University Press, $14.00; 190 pp., illus.*

A few months ago, a vociferous group of animal welfare organizations cornered a big American corporation and made history for their cause. Revlon Inc., besieged by protests that it was cruel to use laboratory rabbits to find out if its eye makeup might irritate customers' eyes, gave three-quarters of a million dollars to Rockefeller University to develop tests that would not use—or maybe misuse—live animals.

The company's humane action came, not from the heart, but from the bottom line, the threat to its good name and profits. In surrendering, Revlon may have felt that it had been sandbagged by a band of zealots. But, as it could discover by reading *Reckoning with the Beast,* the company was really being pushed by one of the most pervasive forces in our society: the animal protectors, who according to author James Turner represent "a new and distinctly modern sensibility."

Unlike so many recent books on our inhumanity to animals, which veer between emotionalism and pragmatism, *Reckoning with the Beast* is cool-headed history, ironic rather than indignant in tone, wide-angled rather than tunnel in its vision. Awesomely researched but admirably brief, it gives a lucid background for the current arguments over animal rights, a term that has joined civil and women's in the contemporary litany of rights.

The term itself is not new. Jeremy Bentham in 1780 matched the rights of animals to the revolutionary doctrine of the rights of man. For centuries before that, however, the idea that animals had any rights went against the grain of Western thought, which denied them a reasoning soul. Ergo, neither the concept of cruelty nor of pity could be applied to animals. A mischievous thinker like Montaigne might, in the sixteenth century, remark that it was only man's vanity that set him apart from his "fellow members and companions" of the animal kingdom. But not until the eighteenth century was the companionship generally recognized.



The concept was expressed in two quite different works. In 1776, a British cleric named Humphrey Primatt published *A Dissertation on the Duty of Mercy and Sin of Cruelty to Brute Animals.* He put forward the radical idea that "pain is pain whether it is inflicted on man or beast." Inflicting it on either was equally evil. The same message went out from the first English book of children's fiction, *Goody Two-Shoes,* whose heroine, Marjorie Meanwell, set an example for all children by tirelessly rescuing suffering cows and horses.

The dread of pain, Turner holds, is "uniquely characteristic of the modern era." The concept that animals feel pain as people do was the basis for the animal protection movement that sprang up so rapidly in England and America in the nineteenth century. The first of many cruelty to animals bills was introduced into Parliament in 1809 by a former Lord Chancellor who had, among his many pets, a goose and two leeches. And even earlier, a jury in Boston, which actually had no law to go by, had indicted a man for the "depraved" beating of his horse.

The original Society for the Prevention of Cruelty to Animals was formed in London in 1824. It drifted along until an inventor named Lewis Gompertz took over. Although very effective, Gompertz was somewhat eccentric—he refused to eat meat or milk or ride in a horse-drawn carriage—and he was a Jew. It was only after he was eased out of office that the peerage became the society's governing body and Queen Victoria graciously permitted appending "royal" to the title. The RSPCA thrived.

This was noted by Henry Bergh, a rich young American who, though

he had no particular love for animals (and actually hated cats), was appalled at the way animals were abused. He was also impressed by the high social status of the RSPCA, and in 1866 he recruited New York's leading citizens to form the American Society for the Prevention of Cruelty to Animals. Dues were set at a high $10 a year, which only the well-off could afford. Other cities quickly followed this example. In Boston, a self-made lawyer named George Angell gained the social standing he longed for by his prodigious work in the local society. Philadelphia women, who were not allowed to hold office in that city's society, formed their own and virtually took over the protection of four-footed Philadelphians. The groups were not democratic, but they got things done.

The richness of *Reckoning with the Beast* lies in the way Turner relates the beginnings of the animal welfare movement to other social forces of the times. It was linked, both in its impulses and the people it involved, to a new Victorian temper, an emphasis on compassion that was "part and parcel," says Turner, "of the separate bundles of worries, ideas and emotions" brought on by the stunning succession of political, industrial, and scientific revolutions. The same reformers who fought to abolish slavery and the exploitation of child workers also fought to stop cruelty to animals.

But for most people who joined the movement, kindness to animals was a comfortable middle-class cause—an outlet for compassion that did not involve politics, as abolition did, or invade family rights, as child protection might. It provided, says Turner wryly, "relief from the internal discomforts involved in digesting fundamental social changes." And when the doctrines of Darwinism "raised disturbing questions about people's own animality, compassion helped quiet them."

Compassion was inevitably diluted by the Victorian genius for sentimentality. "Educate the hearts of the people and the heads will take care of

themselves," was the approach used to teach the common people the virtue of being kind to animals. Whatever their method, says Turner, the Victorians "did enshrine a sympathy for suffering, and not only for suffering animals, among the dominant values of Anglo-American cultures."

The sympathy found several outlets. The new fashion for pets was encouraged by Harriet Beecher Stowe's lump-in-the-throat description of a dog as "nothing but organized love, love on four feet that would die for you, yet cannot speak." A vegetarian sect called the Dorrilites settled in Vermont in the 1790s, but the mainstream of this movement had its source in the precepts of a British Swedenborgian named Cowherd whose disciples settled in Pennsylvania in 1817.

The antivivisectionists were a reaction to the paradoxical actions of science. First, scientists gave a rational base to the animal welfare movement by establishing the biological relationship between humans and beasts. Then exploited this relationship to experiment on animals in order to find cures for human ills. That brought the antivivisectionists charging in to stop the scientists in their "inhumane" acts. They accused experimenters of gothic horrors: "men of science disembowel living horses and open the brains of dogs." Compassion and goodness counted for more than knowledge, they declared, and doubted that vivisection had any use at all. Such doubts were blown away once and for all in 1894 when, after years of testing on animals, two Americans produced an antitoxin for diptheria. This not only conquered a frightening disease that killed two of every five infants that contracted it but also routed the antivivisectionists. They became more concerned—as most are today—with restricting animal experiments than with abolishing them.

Although Turner ignores the instructive role of nineteenth-century naturalists, he does pay attention to today's environmentalists, whose humane impulses, he observes, are directed at all nature, not just one part of it. Their new concern for man's place in nature, he suggests, was born "from the unlikely womb of the Victorian love for animals."

Turner does a remarkable job of encompassing his many-faceted history in a short 140 pages. His bibliographic notes run a quarter as long as his text and are, in themselves, an engrossing index to the ramifications of the subject. Out of his studies, he spins convincing analyses, although it is sometimes disconcerting to read, afterward, that they are not documented fact but considered speculation. Still, the caveats are always there, even if the pace of the book might pull the reader too quickly past them.

Turner could have paused from time to time to tell more about some of the people he presents. Queen Victoria is described as "the kingdom's most prominent antivivisectionist," and that is all we get on her. Henry Bergh's foibles are detailed but not the courage that sent him out, tophatted and armed only with a piece of paper from a judge, to stop brawny carters from lashing their horses and bloody-handed abattoir workers from mindlessly adding to the agonies of their victims. In fact, none of the unyielding dedication of the humane leaders comes through nor is it made plain that an iron rod of Christian duty reinforced Victorian sentimentality.

By design, Turner limits himself to England and America, never explaining the attitudes of other Western countries. This is not a complaint, however, but a regret. Turner's adept scholarship, his perceptions of social history, and his frequent wit make *Reckoning with the Beast* an enlivening exposition of values we take too much for granted. And the jacket of the book is, in itself, an inspired comment. It is a painting by George Stubbs of a monkey looking out at his human kin with wise and wary eyes and evoking a question: Which beast should be reckoning with which?

Joseph Kastner, a former editor of Life, *and that magazine's first nature editor, is the author of* A Species of Eternity *(Knopf), a history of early American naturalists.*

Painting by George Stubbs, Walker Art Gallery, Liverpool

Main intersection at a Hollywood oil field.

"This is the set where they shot 'Hello, Dolly!' What you can't see is us pumping oil behind it."

"One of the strangest places I ever produced oil," says Gulf Production Superintendent Eddie Culbertson, "was right here in Los Angeles, in the back lot of the 20th Century-Fox studio.

"They found an oil field right under a permanent set being used for shooting the movie 'Hello, Dolly!' in 1969.

The indirect approach

"How do you get at the oil without disturbing the set, the streets, or the buildings? With a technique called directional drilling. The oil is as far as one mile from the surface location of the drill sites, which were hidden by the scenery.

"We showed them how they could have their oil and their movies."

"Directional drilling has other advantages. You can drill 20 or 30 wells from just one drill site. Or you can drill for some offshore oil without putting the drilling rig right in the water.

"Behind the scenery are 22 producing oil wells."

Keep America beautiful

"Sometimes it's a real challenge getting the oil without spoiling the landscape. Directional drilling is one way to do it.

"But there are other ways, and at Gulf we're using all of them—doing all we can to keep supplying energy for tomorrow."

Gulf

Gulf people: energy for tomorrow.

Gulf Oil Corporation.

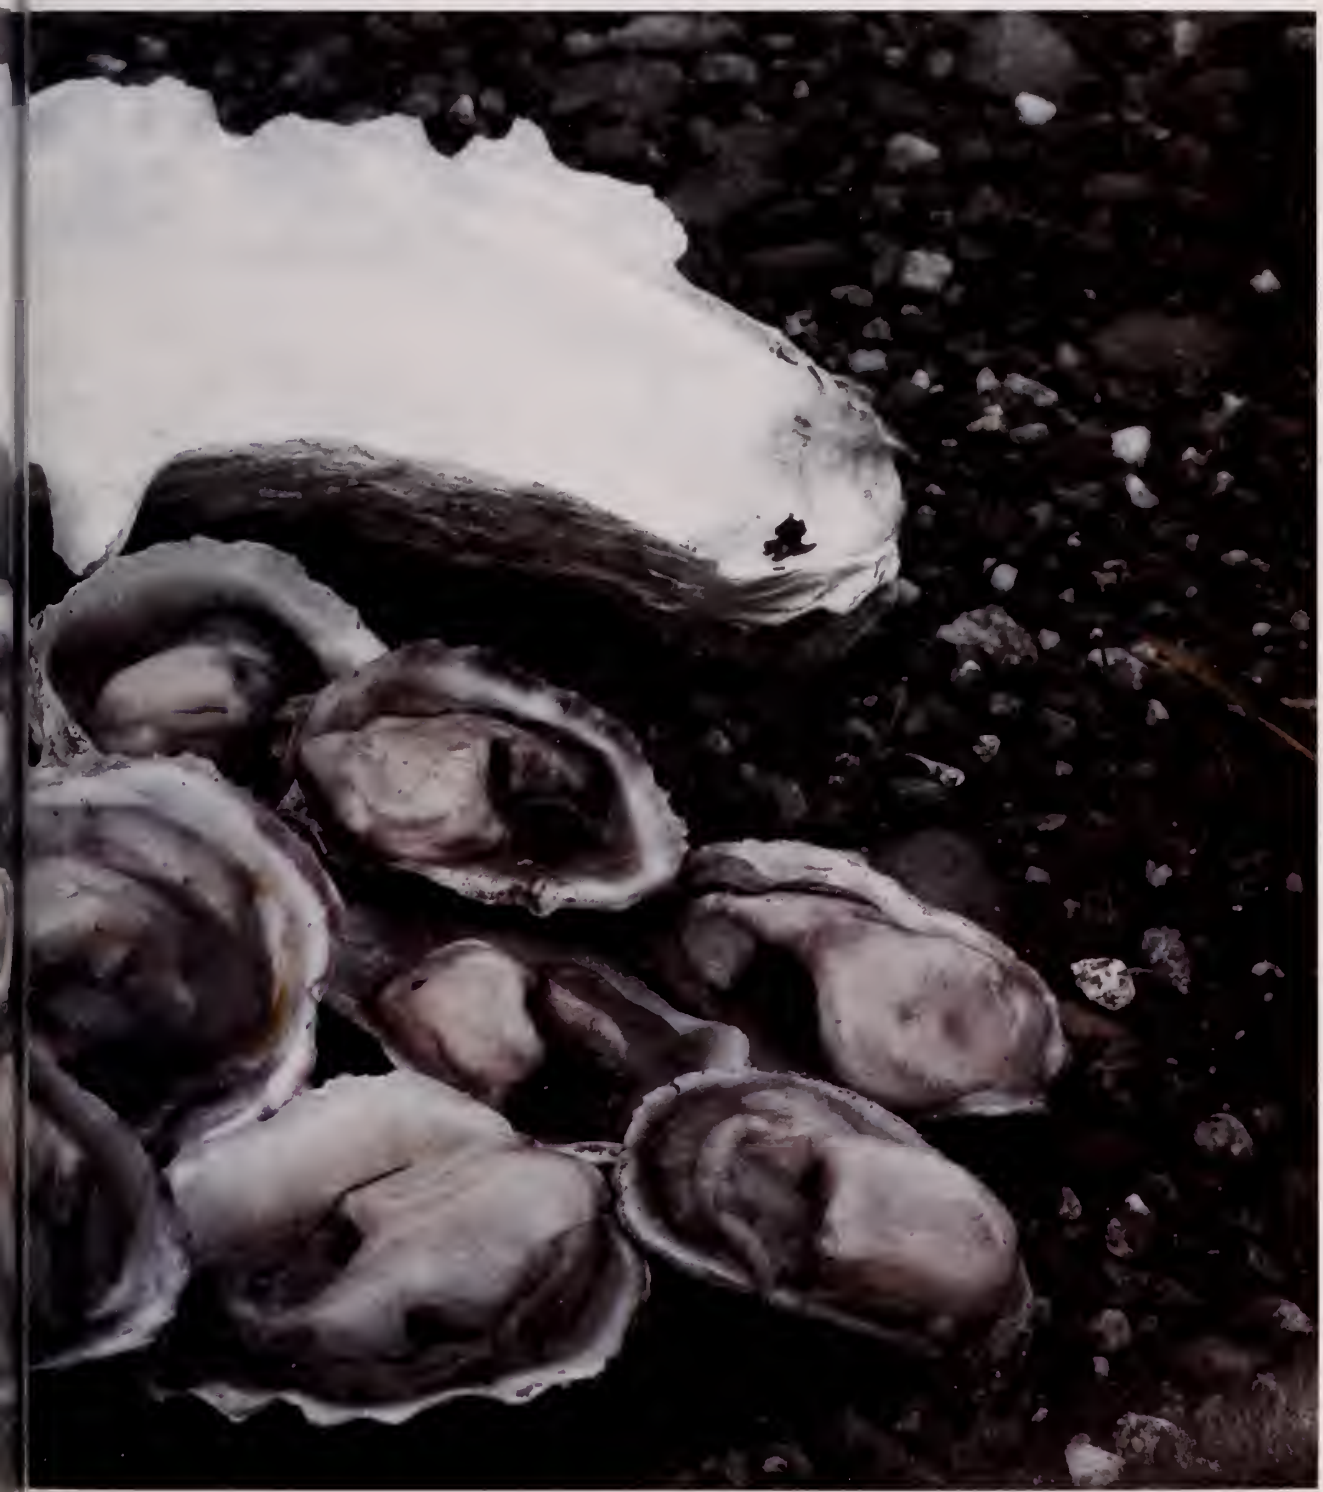
Olympic Trials

The native Olympia oyster of the Pacific Northwest is so rare that it is almost never seen

by Raymond Sokolov

"A loaf of bread," the Walrus said,
"Is what we chiefly need:
Pepper and vinegar besides
Are very good indeed—
Now if you're ready, Oysters dear,
We can begin to feed."
But answer came there none—
And this was scarcely odd because
They'd eaten every one.

Lewis Carroll
Through the Looking-Glass



Oysters naturally just stay put, lying in their salty beds, waiting for people to eat them. As Saki put it, "There's nothing in Christianity or Buddhism that quite matches the sympathetic unselfishness of an oyster." Taking advantage of such complaisance has been a human habit since prehistoric times. And in each place where people have found abundant colonies of oysters, they have attacked them wholesale, downing dozen after dozen, until what had begun as a cheap snack for Everyman was so depleted that only the wealthy could continue to feast with traditional abandon.

In Britain today, Colchester oysters are now a luxury, but in Dickens's *Pickwick Papers* (1837), Sam Weller observes: "Poverty and oysters always seems to go together." The same process occurred in this country, where early settlers on the Atlantic coast considered oysters poor people's food, and contemporary New Yorkers pay a premium price for increasingly scarce specimens of *Crassostrea virginica*. On our Pacific coast, the situation is far worse.

The native Olympia oyster, *Ostrea lurida*, is so rare that it is almost never seen, even in the state of Wash-

Delicate "Olys" (foreground), the native Olympia oysters, are smaller and tastier than the large Pacifics that have replaced them.

Photographs by Adelaide de Menil

A large pile of oyster shells outside the Skookum Bay Oyster Company

ington, where it was once an important feature of the local economy. The tiny, 1½-inch-long bivalve, with its distinctive violet-tinged inner shell walls and intense marine taste, was a unique and toothsome part of pioneer days in the Pacific Northwest. Delicate "Olys" were the favored sweetmeat of Gold Rush San Francisco. In our ill-favored era, there are none for sale in San Francisco. Why you cannot even buy one at an oyster bar in Seattle. Instead, you find insipid Pacifics (*Crassostrea gigas*) grown locally from Japanese seed. They are huge, attaining a length of ten inches, and they grow fast. Young ones, eaten directly from the shell, do have a certain tang to them. But full-size Pacifics, shucked industrially and assiduously washed—the normal practice on the West Coast—are as flat in flavor as a hunk of wet foam rubber. Meanwhile, the elegant little Oly has all but vanished into the folklore of Puget Sound and the Northwest Coast.

James G. Swan, an early settler in the Washington Territory—and a pioneer Indian ethnographer, inveterate diarist, debauchee, and opportunist—worked in the oyster business in its infancy during three years (1852 to 1855) he spent at Shoalwater Bay. Swan, who took a precise interest in what he ate, wrote of the "strong, coppery taste" of the Shoalwater Bay oysters, which he attributed to the mud flats where they grew. "What is called a coppery taste," he went on, "is simply a strong, fishy, salt-water flavor, which, however, is driven off by cooking."

Taste changes over time, and the coppery, "fishy" taste Swan boiled or fried away is probably the taste modern oyster lovers seek. Still, it is risky to rely on descriptions of flavor from the past. After all, in his memoir of Shoalwater Bay, *Oysterville*, Willard R. Espy states that "the Puget Sound oyster, known as the Olympia, had a copper taste offensive to refined San Francisco palates. But the same gourmets who rejected the Olympia oysters sang hosannas" to the oysters of Shoalwater Bay.

Presumably, all those Northwest Pacific oysters in the middle nineteenth century were examples of *Ostrea lurida*, what we would call Olympias. Their coppery taste, or lack of it, will probably remain a subject of gastronomic confusion. There is no

doubt, however, that literally tons of oysters were consumed after gold was struck in California. San Francisco Bay was stripped bare first. And so the devastation went, on up the coast. Puget Sound was the most remote source and held out longest.

At the turn of the century, whole communities of oyster folk lived and worked on float houses in the tidal inlets of southern Puget Sound near Olympia. Steamers came daily to Mud Bay, Oyster Bay, and Little Skookum to pick up sacks of Olympias. To fill those sacks, oystermen and their families worked through the night, when the tide was usually out and the oysters could be raked from the mud flats.

Cora G. Chase spent part of her childhood, from 1898 to 1914, on a float house in Oyster Bay. In a memoir, written as a research paper at the University of Washington in 1944, she interviewed one of the pioneer oystermen, Dick Helser, an old neighbor at Oyster Bay:

> He worked his own bed in the early days, getting up at night according to the tides, raking oysters in windrows around a float that had been staked out when the tide was in, then forked them up into the float by lantern light. In the gray of cold winter mornings the loaded float was "poled" to the culling house anchored some distance from shore. There the oysters were forked into a sink float, an upside-down float holding two feet of water to keep the oysters fresh.
>
> From the sinkfloat they were forked into a wheelbarrow, rolled into the culling house, up a plank and dumped onto the culling table. All day long the cullers sorted out the larger oysters, knocking off barnacles, smaller oysters and debris with a culling iron (a thin piece of metal easily grasped) and dropping the marketable oysters into a five-gallon kerosene can, then raking the cullings down the hopper at the edge of the table.

Cheap child and nonwhite labor kept the barnacles and oyster shells flying and filled the sacks with precious mature Olympias. Many hands, chilly from long days and nights of dull work in the damp and cold, made rapid work of the depletion of Washington's natural oyster beds. By the nineties, it was necessary to construct artificial beds, diked so that water would shelter the seeded oysters from extremes of heat and cold. Chinese did the work for ten cents an hour. Today, it costs $12,000 to construct an acre of oyster beds, according to Vivian Ellison Bower of Ellison's Oyster Company outside Olympia. At that price, no one is building new beds for Olympias anymore. In fact, almost no one is even seeding the old beds anymore. "Everyone's given up," says Mrs. Bower. "It's all hand labor and takes four years."

Olympias mature slowly and never get very large. Inevitably, they have lost out to the larger Pacific oysters. The decline has gone so far that it is virtually impossible to taste an Oly without going to Olympia itself, and even there the line of supply is very thin.

The only restaurant in town (and probably the only restaurant in the world) that makes a practice of serving Olympias is the historic Olympia Oyster House. On one of the walls is a framed menu from 1921 listing an Olympia oyster stew for 30 cents. Today the restaurant's menu still lists Olympias but gives no price. Instead, in parentheses, it warns that "market" will determine the cost of the oysters, "when available."

"We used to ship them fresh anywhere," the manager told me. "Now we buy a gallon or two at a time."

For a plate of crisply fried, breaded Olympias I paid $16.95, which was fair enough for so rare an item. But all that breading and cooking had effectively removed too much of the oysters' essential flavor for me to get a true impression of their taste. I wanted freshly opened Olympias on the half shell, but the Olympia Oyster House bought them already shucked from a supplier.

Of the several oyster companies in the Olympia area, only two process Olympias. The Olympia Oyster Com-

Olys are shucked with a special scaled-down oyster knife

pany opens only three to four bushels a week and didn't happen to have any in stock when I passed through. But the Skookum Bay Oyster Company, a family operation located on a small bay in the hinterland of Shelton, Washington, at the end of a dirt road, is in its gray way a landmark of contemporary American gastronomy. It processes Olympias with regularity.

Outside the company's weathered building, you notice a derelict boat and big piles of oyster shells. Some of those piles are made of tiny, irregular, purple-tinted shells, which thousands of Olympias once lived in.

Inside, John Blanton supervises his little factory. In the first work area one comes to, a woman jabs at humongous Pacifics, flipping them out of their shells like great pale tongues. In back, Blanton's grown daughter Donna works more delicately, with a scaled-down oyster knife especially modified for Olys. Donna can open roughly 4,000 of them on an average day, about two gallons of shucked Olys altogether. Her brother culls the day's load of mud- and shell-filled pickings from the family's Olympia beds. He passes a small number of harvestable oysters on to his sister.

The scene is not quite as romantic as the floating world of Oyster Bay that Cora Chase describes. But the Blantons are certainly in the same tradition.

Donna let me fumble with her knife until I got an oyster open. Straightaway, I sucked the thumbnail-sized mollusk out of its shell.

The taste was sharply marine but also refined, and in no way did it remind me of copper. I confirmed this judgment some hours later at the place where Dungeness Spit arcs out in a thin ray of sand for miles into the Strait of Juan de Fuca. Sitting on driftwood in the perpetual drizzle, I devoured thirty or more shucked Olys, feeling favored but wondering why tradition-crazed Westerners and the Northwest Coast's rabid environmentalists haven't put their money as well as their mouths behind the preservation and encouragement of a unique, vanishing, and most toothsome native bivalve. If we are finally ready as a nation for the small car, why not also insist on our right to the small oyster?

Raymond Sokolov, a writer with an interest in the history and preparation of food, is editor of Book Digest.

Doane's Pan Roast
(Courtesy of Olympia Oyster House)

1 pint shucked oysters
2 tablespoons butter
3–4 tablespoons ketchup
Pepper
Toasted bread

1. Wash oysters well.
2. Put in a pan and let come to a simmer. Immediately add butter, ketchup, and pepper. Stir gently and serve on toasted bread as soon as butter melts.

Yield: Two servings

Lila Gault's Northwest Oyster Stew
(Adapted from *The Northwest Cookbook*; Quick Fox, Inc.)

1 pint shucked oysters
1 cup heavy cream
3 cups milk
1 teaspoon salt
1 tablespoon Worcestershire sauce
Cayenne
2 tablespoons butter
Chopped parsley

1. In a large Dutch oven, simmer oysters in their liquor over low heat for about three minutes or until the edges begin to curl. Add cream and milk, and heat until bubbles form around edge of pot, but not until boiling.
2. Add salt, Worcestershire, and cayenne in small amounts to taste.
3. Remove from heat and add butter. Garnish with chopped parsley.

Yield: Four servings

Cover: *The stork is one of the birds represented in French naturalist Pierre Belon's* L'Histoire de la Nature des Oyseaux, *published in 1555. This book and other selections from the Folger Shakespeare Library will be shown at the American Museum from June 18 to September 20 in a special exhibit, "Shakespeare: The Globe & the World." Story on page 54.*

After analyzing land surveyors' notes, U.S. Bureau of the Census statistics, and inventory records from the U.S. Forest Service, **Hazel R. Delcourt** was able to reconstruct the changing patterns of land use and carbon storage in the Southeast over the past 250 years. She has recently expanded her work to include all of the eastern United States. A research associate at Oak Ridge National Laboratory in Tennessee, Delcourt also pursues her interest in vegetational and climatic change through the study of pollen and plant macrofossils preserved in the sediments of lakes and bogs. Together with her husband, Paul, she hopes in the future to calibrate "modern forest composition with atmospheric pollen samples in order to reconstruct forest history in the eastern United States for the past 20,000 years."

While studying migration and ethnicity in Ghana, **Enid Schildkrout** (right) noticed that to assist them in their home industries, women often decided to raise children who were not their own and that women earned more when they had such children to help them. Having learned the Hausa language in Ghana, she set out for northern Nigeria in 1976 to explore the economic roles of women and children more deeply. Schildkrout holds a doctorate in social anthropology from Cambridge University and is the author of *People of the Zongo: The Transformation of Ethnic Identities in Ghana.* Since 1973 she has been an associate curator in the American Museum's Department of Anthropology.

When the Folger Shakespeare Library in Washington, D. C., decided to mount a traveling exhibition drawn from its wide-ranging collection of materials related to the Bard of Avon and his age, Shakespeare scholar **Sam Schoenbaum** was given the task of writing an accompanying catalog. Although it meant delving into subjects with which he could "claim only amateur status"—such as the flora and fauna of Warwickshire—Schoenbaum took on the assignment with enthusiasm. "I was here given occasion to study many unique items for the first time," he comments in the catalog's preface. "Meanwhile, the books and manuscripts already long familiar to me retained their magic; the honeymoon is still on." Distinguished Professor of Renaissance Literature at the University of Maryland, Schoenbaum is currently coediting the *Complete Oxford Shakespeare.* The article in *Natural History* is adapted from his Folger exhibit catalog.

John A. Byers, an assistant professor of zoology at the University of Idaho, writes that his interest in peccaries began in 1976. He had been studying play in Siberian ibex at the Brookfield Zoo in Chicago. The peccary enclosure was near the ibex exhibit, he says, and the peccaries caught his eye: "I did some reading about them and realized that very little was known about their social behavior. There were fascinating hints in the literature suggesting that peccaries were highly social and this led me into my fieldwork in Arizona." Byers is now beginning a five-year project on the relationship between variation in behavioral development and subsequent variation in reproductive success in pronghorn antelopes. The research will be done at the National Bison Range in Montana. Byers enjoys Eastern European novels and beer, and says that he is tired of people sending him items with pig motifs.

The next picture you take with your 35mm SLR can be as creative as any of these.

With the most creative new idea in photography.

The Cokin Creative Filter System is a totally new way to perform creative miracles using any 35mm SLR: Canon, Leica, Minolta, Nikon, Olympus, Pentax and others. And it's easy, too. Send a dollar for the full-color Cokin guide with 158 stunning examples of the imaginative effects you can achieve. Please allow four to six weeks for delivery.

The Flood of Antievolutionism

Where is the science in "scientific creationism"?

by Laurie R. Godfrey

In 1963, American historian Richard Hofstadter wrote that "today the evolutionary controversy seems as remote as the Homeric era." The Biological Sciences Curriculum Study Project, supported in part by federal funds, was preparing secondary school texts that openly presented evolution as the foundation of biology. And George McCready Price, an outspoken leader of the protest against evolution in the days of the Scopes "monkey trial" and author of numerous antievolutionary tomes, including *The Phantom of Organic Evolution* (1924), *A History of Some Scientific Blunders* (1930), *The Modern Flood Theory of Geology* (1935), and *Genesis Vindicated* (1941), died at the age of 92. But 1963 was also the year that the Creation Research Society—and with it, organized "scientific creationism"—was born.

The Creation Research Society was founded by a group of ten men led by Walter E. Lammerts and William J. Tinkle. Many of these men were disaffected members of the American Scientific Affiliation, a theistic organization founded in 1941 and devoted to the reconciliation of science and evangelical Christianity. The increasing domination of the organization by evolutionists disturbed those who wanted it to oppose evolutionism. The "team of ten" vowed to work, through what they regarded as scientific endeavors, for a revival of belief in special creation as described in the King James version of the Bible. While they held populist William Jennings Bryan, the Scopes prosecutor, in high esteem, the new activists were creationists of a different ilk.

Bryan had mocked his scientific opponents: "You believe in the age of rocks; I believe in the Rock of Ages." He had preached to the masses, "I would rather begin with God and reason down then begin with a piece of dirt and reason up." But the new creationists profess no disdain for science. College-educated fundamentalist Christians with a strong commitment to both science (particularly in the form of technology and engineering) and to a literal interpretation of the Bible, they have set out to convince the public that "true science" supports the creation model of world and life origins. Denying that they are trying to bring religion into the public schools, they are seeking to have their model taught as science.

By the end of 1980, seventeen years after Hofstadter had pronounced the evolution controversy dead, "two-model" scientific education bills—which would require public schools to present creation as a scientific model alongside evolution—had been introduced and debated in the state legislatures of Florida, Georgia, Illinois, Iowa, Kentucky, Louisiana, Minnesota, New York, South Carolina, Tennessee, and Washington and were being introduced elsewhere. In addition, various local school boards around the country had passed resolutions that made concessions to creationist pressure. The membership of the Creation Research Society, based in Ann Arbor, had grown to 2,500. Sister organizations such as the Bible Science Association (Minneapolis), the Creation Social Science and Humanities Society (Wichita), the Institute for Creation Research and the Creation Science Research Center (San Diego) had been formed to defend scientific creationism and promote the teaching of creation as equal with evolution.

Led by virtually the same nucleus of antievolutionists, these organizations have become efficient factories of purportedly scientific antievolutionary propaganda. Conventions, as well as debates, textbooks, and films, are the means to the political end of building a constituency. The Institute for Creation Research (ICR) now offers college- and graduate-level programs as well as summer institutes (offering optional college credit) on creationism; distributes antievolutionary books, pamphlets, and cassettes; and sponsors creation/evolution debates and nationally distributed weekly radio broadcasts. And the ICR also funds research: to find evidence of Noah's ark and a global flood; evidence of coexisting humans, trilobites, and dinosaurs; and proof of a recent creation of the universe and the planet Earth (the earth is assumed to be roughly 10,000 years old). The Creation Research Society developed the first "creation science" biology textbook meant for use in public secondary schools, and since 1964 the society has published a quarterly journal dealing with evidence that supports a literal interpretation of the Bible.

The scientific creationists make no attempt to hide the proselytizing role of their various research organizations. Emphasis Creation 1980 was a Midwestern convention of scientific creationists sponsored jointly by the ICR and the Bible Science Association. The Director of the ICR, Henry Morris, gave explicit instructions, which appeared in the newsletter of the ICR's Midwest Center:

Roam the world with ease

Now MasterCard™ Travelers Cheques.

Now a Travelers Cheque
bears the MasterCard symbol.
Respected, recognized and accepted the
world over. Refundable and replaceable
twenty-four hours a day, so you can travel
truly care-free.
Next trip, roam the world with ease, with the wind
at your back. Ask for MasterCard Travelers Cheques.
Next trip,
Run With the Wind.

The purpose of such a convention should not be to provide a forum where various creationists get together to present papers arguing for their own particular interpretations on details of science or Scripture. Rather, it should seek to reach as large and general an audience as possible with carefully chosen papers (and other activities) by qualified speakers who will make the greatest impact for the creationist cause in general.

The newsletter went on to list acceptable and unacceptable topics. The former included refutations of evolutionism; legal, political, and educational aspects of teaching creation in schools; scientific evidence for a recent creation of the earth and universe; and "flood geology," which attributes a wide range of fossil-bearing geologic deposits to a single catastrophic global event, the Noachian deluge. Unacceptable topics included plate tectonics and continental drift (listed among others as areas of questionable or peripheral significance to creationism) and all "highly technical and specialized treatments of individual problems."

Field or laboratory research represents a very minor charge of scientific creationists. Most efforts are directed toward rewriting the discoveries and interpretations of evolutionists. In this endeavor, numerous evolutionists are portrayed as scientists who have all the evidence to disprove evolution (and support creation) at their fingertips, but who are either too stubborn or too deeply indoctrinated in evolutionary dogma to appreciate it. Arguments of anthropologists, biologists, chemists, geologists, astronomers, physicists, and engineers are reinterpreted or taken out of context. In this way, as I will show below, creationists manage, among other things, to convert arguments about the pattern and process of evolutionary change into arguments about the existence of change.

The primary tactic of the scientific creationists is to find controversy, disagreement, and weakness in evolutionary theory—by no means a difficult task. Having demonstrated problems with various aspects of evolutionary theory (some fabricated, some real), the creationists then conclude that we must accept the Judeo-Christian biblical account of creation as the only possible, logical alternative. Thus scientific creationism proceeds by constructing an artificial dichotomy between two models—evolution and creation—both incorrectly represented as monolithic.

Actually, various evolutionary explanations are possible, and numerous models, both Darwinian and non-Darwinian, have been posed. They have in common the notion that the earth's life forms are related by common ancestry, whether or not they have since achieved reproductive isolation. Evolutionists agree that the evidence supports this premise of genetic continuity although, as scientists, they do not rule out the logical possibility that life could have arisen independently on more than one occasion on the earth or in the universe.

Creationism, on the other hand, is based on the idea that reproductive isolation usually signals the absence of common ancestry. Given genetic discontinuity, numerous creation-based explanations are nevertheless possible: witness the global diversity of creation myths. Ignoring this diversity, however, scientific creationists begin with one specific and detailed explanation of the universe and require its acceptance on faith as a prerequisite of membership in their various research organizations. The Statement of Belief of the Creation Research Society begins: "The Bible is the written Word of God, and because we believe it to be inspired throughout, all of its assertions are historically and scientifically true in all of the original autographs." The scientific creationists do not pose and test alternative creation models. Doing science is not the business of scientific creationists; destroying the public credibility of evolution is their real goal. "New evidence," the press is told, reveals "major weaknesses" in evolution. Oddly, the creationist tactic of discovering controversies within evolutionary biology amounts to discovering that evolutionary biologists are guilty of doing science—posing, testing, and debating alternative explanations.

One scientific debate in particular, that between the neocatastrophists (or punctuationalists) and the phyletic gradualists, has fueled the fires of scientific creationism. In 1972 Niles Eldredge of the American Museum of Natural History and Harvard paleontologist Stephen Jay Gould launched their new theory of evolution by "punctuated equilibria." Evolution, they claimed, proceeds by rapid fits and starts, punctuating long periods of relative stasis. Drawing from the work of other paleontologists and neontologists, Eldredge, Gould, and later, Steven Stanley of Johns Hopkins developed the implications of a punctuational model of evolutionary change. In so doing, they challenged the assumption that most evolutionary change occurs as a byproduct of slow, ceaseless natural selection acting on variation in well-established populations.

While they have not abandoned the concept of natural selection as an important evolutionary process, the punctuationalists have reinterpreted its role. Central to their argument is the view that most evolutionary change occurs in association with speciation, that is, the formation of independent species by the splitting of lineages into reproductively isolated populations. They argue that speciation may be achieved rapidly in small, geographically isolated populations and that, in such populations, chance (as well as natural selection) can exert much greater influence on genetic change in form than is otherwise possible. They further argue that rapid or dramatic evolutionary changes cannot occur in the *absence* of speciation. The mechanisms and im-

From more than 1000 years of tradition and art . . .

The Treasures of the Imperial Dynasties

MINIATURE VASE COLLECTION

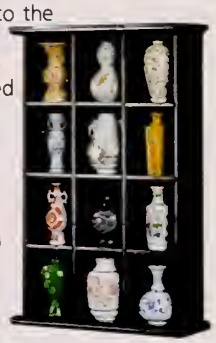
Twelve exquisite miniature vases, re-creating the great porcelain artistry of the Chinese Imperial Dynasties.

A limited edition. Subscription deadline: June 30, 1981.

Imagine a collection of delicate and beautiful vases—authentic re-creations of historic Chinese porcelain designs. Imagine each one a fine miniature, approximately 3" high, and you have a collection to attract the admiration of all who see it.

Now *you* can own *just* such a collection. Twelve exquisite vases reflecting a thousand years of Chinese porcelain art. And, despite the careful craftsmanship involved, the price for each vase is just $12.50.

A treasury of classic porcelain art



Displayed together on the black hardwood shelf provided, the 12 vases form a veritable treasury of porcelain art. A Mei-p'ing vase, in the style of the early Sung Dynasty, when only the Chinese knew the secret of making fine porcelain. A handsome temple vase, one of the earliest examples of blue-and-white ware. With ten others just as beautiful, each crafted in fine porcelain. And to ensure the *highest* standards of quality, Franklin Porcelain has entrusted crafting of the vases to its Tokyo subsidiary.

VASES SHOWN SLIGHTLY SMALLER THAN ACTUAL SIZE

A collection to grace any room in your home

Each vase represents a different era, yet each complements the others, to form a collection fascinating in its diversity. It's as though you personally searched the world's antique marts and assembled this collection piece by piece.

To acquire this intriguing collection, you need send no money now. Please note, however, that it is a limited edition available only until the end of 1981. The total edition will be forever limited to the exact number of valid applications postmarked in this period. But remember: the form below is valid only if mailed by the subscription deadline: June 30, 1981.

© 1981 FP

SUBSCRIPTION APPLICATION

THE TREASURES OF THE IMPERIAL DYNASTIES

Valid only if postmarked by June 30, 1981.

Franklin Porcelain
Franklin Center, Pennsylvania 19091

Please enter my subscription for The Treasures of the Imperial Dynasties Miniature Vase Collection: Twelve fine porcelain miniature vases, plus a handsome black hardwood display shelf at no additional charge.

I need send no money now. My vases will be sent to me at the convenient rate of one per month. I will be billed just $12.50* for each new vase in advance of its shipment.

*Plus my state sales tax and $1 shipping and handling per vase.

portance of speciation lie at the heart of the debate between the punctuationalists and their opponents. Unlike the phyletic gradualists, the punctuationalists conclude that in macroevolution (evolution viewed in the long range and on a large scale), an episodic pattern of change is the expectation, rather than an exception to the rule.

A second important issue in evolution that has attracted the attention of creationists is the question of the relative importance of chance as a factor in evolutionary change. Using computer simulations, David Raup and his colleagues at Chicago's Field Museum of Natural History have argued that chance is very important in macroevolution as well as microevolution. Raup believes that many genetic changes that do not greatly affect "fitness" may survive or fail to survive owing to chance. Such evolution by chance is called neutral, or non-Darwinian, evolution. The debate in evolutionary biology is over its relative importance, not its existence.

It is hard to imagine creationists drawn to the arguments of Eldredge, Gould, and Raup, since they are antithetical to creationist tenets. First, the question of the genetics of speciation, which is central to the theory of the punctuationalist school, is foreign to creationism. "Speciation" is rarely part of creationist vocabulary; "special creation" is used instead. Creationists claim that each life form was created as a separate "kind" (a common-sensical, undefined concept) and that nature permits variation only within such created kinds. Thus they must ignore a large body of biological data on the mechanisms of speciation and examples of its occurrence observed both in the laboratory and the field. Scientific creationists deny the existence of the very process that punctuationalists argue is critical to evolutionary change.

Nothing about punctuationalism supports the creationist viewpoint. Punctuationalists simply maintain that while much evolutionary change is very slow or static, very rapid "jumps" can occur naturally and these are the important stuff of macroevolutionary change. Genetically, such jumps are as comprehensible as slow phyletic changes. Indeed, whether they are perceived as jumps at all depends upon one's expectations concerning the scale and pace of evolutionary change. As Gould has written (*Natural History*, August 1979):

> New species usually arise, not by the slow and steady transformation of entire ancestral populations, but by the splitting off of small populations from an unaltered ancestral stock. The frequency and speed of such speciation is among the hottest topics in evolutionary theory today, but I think that most of my colleagues would advocate ranges of hundreds or thousands of years for the origin of most species by splitting. This may seem like a long time in the framework of our lives, but it is a geologic instant, usually represented in the fossil record by a single bedding plane, not a long stratigraphic sequence.

Second, "chance" is also foreign to creationism. One Florida-based organization puts out a flier that reflects the widespread creationist notion that nothing (or nearly nothing) ever happens by chance: "Evolution demands what has not, and cannot happen, even with careful planning—much less by total accident!" It is, of course, a misstatement of evolution to claim that this body of theory argues that change comes about "by total accident," for selection is not a random process. Yet, the non-Darwinian school ascribes to chance a much more central role than is admitted by other evolutionary biologists. Ironically, in their effort to show disagreement among evolutionists, the creationists are citing the work of paleontologists whose arguments are, in many ways, the most antithetical to creationism.

One reason creationists are able to exploit the current debates among evolutionists is that certain key phrases have entirely different meanings for paleontologists and for creationists (or their constituency). When such phrases are lifted from the work of evolutionists and inserted into creationist literature, they acquire new meaning simply because of differences in assumed knowledge. For example, the "neocatastrophism" of paleontology (widely quoted in support of creationist catastrophism) has nothing to do with either creation or a great flood. But creationists automatically associate the term "catastrophism" with the concept of the Noachian deluge.

Creationist Gary Parker wrote an essay on neocatastrophism that was circulated in the October 1980 issue of *Acts and Facts*, the free monthly newsletter of the ICR. Reading his article one cannot avoid the conclusion that Raup and Gould consider the creation model tenable, if not actually preferable to evolutionism. Here is a passage from Parker's essay:

> "Well, we are now about 120 years after Darwin," writes David Raup of Chicago's famous Field Museum, "and the knowledge of the fossil record has been greatly expanded." [Parker cites a 1979 article by Raup.] Did this wealth of new data produce the "missing links" the Darwinists hoped to find? ". . . ironically," says Raup, "we have even fewer examples of evolutionary transition than we had in Darwin's time. By this I mean that some of the classic cases of darwinian change in the fossil record, such as the evolution of the horse in North America, have had to be discarded or modified as a result of more detailed information." Rather than forging links in the hypothetical evolutionary chain, the wealth of fossil data has served to sharpen the boundaries between the created kinds. As Gould says, our ability to classify both living and fossil species distinctly and using the same criteria "fit splendidly with creationist tenets." "But how," he asks, "could a division of the organic world into discrete entities be justified by an evolutionary theory that proclaimed ceaseless change as the fundamental fact of nature?" [Parker cites a 1979 *Natural History* article by Gould.] ". . . we still have a record which *does* show change," says Raup, "but one that can hardly be looked upon as the most reasonable consequence of natural selection." The change we see is simply variation within the created kinds, plus extinction.

The arguments Parker presents outside, as well as inside, quotation marks seem to be those of Raup and Gould. Given these selected tidbits, there is no way to interpret the statements of Raup and Gould except within the framework of the creation model. The reader is not told what Raup and Gould are arguing but is left instead to surmise, incorrectly, that evolution itself is under attack. Furthermore, Parker has chosen to cite titles that seem to support such an interpretation. Raup's article is called "Conflicts between Darwin and Paleontology." Gould's is entitled "A Quahog Is a Quahog."

Those familiar with Raup's research will not be surprised to find that his article is actually a treatise concerning problems with Darwinian gradualism. Raup first deals with the complex, uneven record of evolutionary change. His point, quoted more fully, is that "some of the classic cases of darwinian change in the fossil record, such as the evolution of the horse in North America, have had to be discarded or modified as a result of more detailed information—what appeared to be a nice simple progression when rel-

atively few data were available now appears to be much more complex and much less gradualistic." Raup goes on to discuss the potential of chance processes to bring about apparently patterned evolutionary change—in particular, the extinction of lineages.

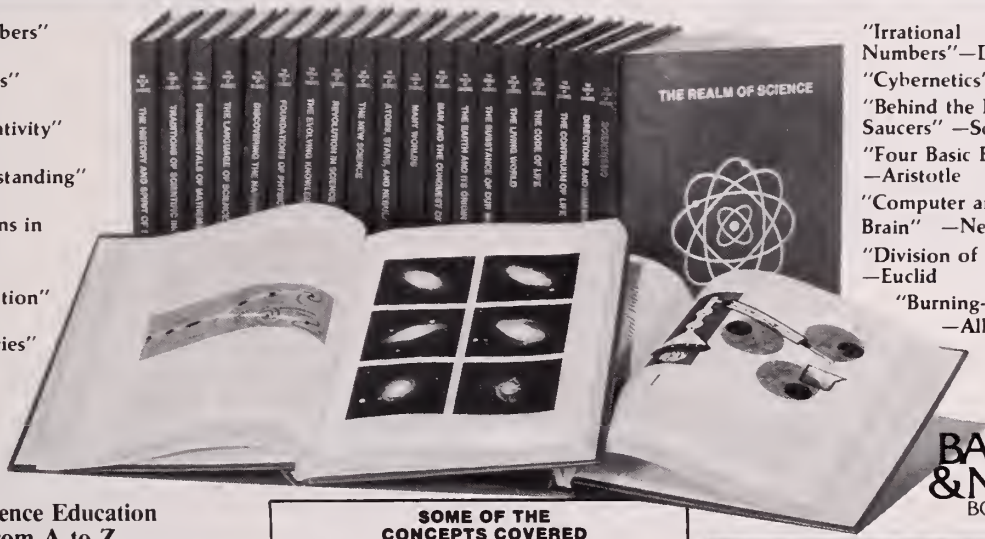
Gould's article is also about problems with Darwinian gradualism. It takes to task those biologists and anthropologists who argue that species boundaries are artifacts of the human capacity to classify and construct artificial divisions. Gould argues, as Ernst Mayr did years before, that species are real biological entities, but he does not suggest that they are genealogically unrelated to one another or that they cannot give rise to new species.

Despite the attempts of scientific creationists to play up the signs of controversy among evolutionists, there is actually widespread agreement in scientific circles that the evidence overwhelmingly supports evolutionism. Confirmation has sometimes taken unexpected forms, as in the high correlation between the degree of biochemical difference between pairs of species and the amount of paleontological time since their apparent separation.

There is agreement that the pattern of origin of taxa in the paleontological record strongly supports genetic continuity and, therefore, evolution. The punctuationalists' concept of evolutionary stasis has been misused by creationists to argue against such a pattern, but evolutionary stasis contradicts only strict gradualism, not evolution. The fact is, the genus *Homo* does not occur in the Mesozoic alongside brontosaurus, as the creationists claim; if it did, we would indeed have to question our evolutionary assumptions.

Scientists do ask questions about the pattern of evolutionary change. In particular, does the fossil record bear witness to the slow, continuous, gradual change envisioned by Darwin and supported by neo-Darwinists? Although still a matter of considerable debate, some form of punctuationalism is gaining increasing support among evolutionists. Scientists also ask questions about the process or mechanism of evolutionary change: for example, given a pattern of punctuational change, is Darwinian natural selection the best explanation for macroevolutionary trends?

The current debate is complicated because the concept of natural selection embraced by Darwinians has changed with the introduction of population genetics. Steven Stanley's concept of species selection (the differential survival of species) is part of natural selection as formulated by Darwin and some modern biologists, but not as formulated by population geneticists focusing on selection operating within populations. Therefore, when Eldredge, Gould, and Stanley proclaim natural selection to be an inadequate explanation of macroevolutionary change, it is important to realize that they are talking about natural selection as mathematized, reformulated, and restricted to populational variation by population geneticists in the 1930s.



When a creationist such as Parker describes the putative failure of natural selection, however, it is to an audience that simplistically equates natural selection with evolution—an audience that does not know the difference between natural selection and species selection. Most students of scientific creationism know little about the debate between the phyletic gradualists and punctuationalists or that between proponents of Darwinian (nonrandom) and non-Darwinian (random) processes of change. And they will not learn what the debates are about from Parker and his colleagues.

"It's so utterly infuriating to find oneself quoted, consciously incorrectly, by creationists," Gould has said. "None of this controversy within evolutionary theory should give any comfort, not the slightest iota, to any creationist." Yet the scientific creationists, by misrepresenting the ongoing work of evolutionists, have helped the antievolutionary cause to gain more momentum than ever before in the twentieth century. Scientific creationists are widely viewed as learned scholars with impressive credentials, and more and more people are being persuaded that staggering evidence is on their side. Many scientists are baffled that such poor science can be so easily swallowed, and that creation is being taught as science in some schools around the country. Scientific creationism may be poor science, but it is powerful politics. And politically, it may succeed.

Laurie R. Godfrey teaches physical anthropology at the University of Massachusetts, Amherst.

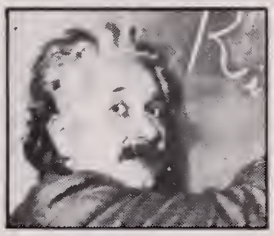
BARNES & NOBLE BOOKSTORES

A Science Education from A to Z



From the *ABC of Relativity* by Bertrand Russell, to Zeno's paradoxes, this 21-volume library provides a complete and fascinating science education.

Unlike an encyclopedia, this reference work is one you can read for pure enjoyment as well as refer to for reliable information. The key to this readability is the fact that THE REALM OF SCIENCE is actually a massive collection of selected writings arranged and indexed by subject. It is so complete, that the cumulative index alone runs almost 200 pages!

Think of a subject, look it up, and read what the world's foremost authorities have written about it.

The Greatest Minds the World Has to Offer

The authorities represented in this priceless collection read like a "Who's Who" in science. There's Priestley on the discovery of oxygen; Faraday on electrochemistry; E.O. Wilson on sociobiology; Ernst Nagel on Godel's proof. Plus Isaac Asimov, Jacob Bronowski, Martin Gardner, Max Planck, James Watson, George Gamow, Fritz Zwicky, and hundreds more. From ancient Babylonia to the present, you will be exposed to the greatest minds the world has to offer.

Einstein's special theory of relativity changed our concept of time, distance and mass.

A Valuable Research Tool

Although each volume contains its own index, the unique Science Concept Index "brings it all together." It will help you find vital information on a given subject, person, place or idea throughout the set. It will also enable you to trace various applications of a subject from one author to another, from one concept to another, or from one discipline to another. Imagine what a valuable research tool this can be. Taken as a whole, this 21-volume set provides an overview of science never before possible in a single work.

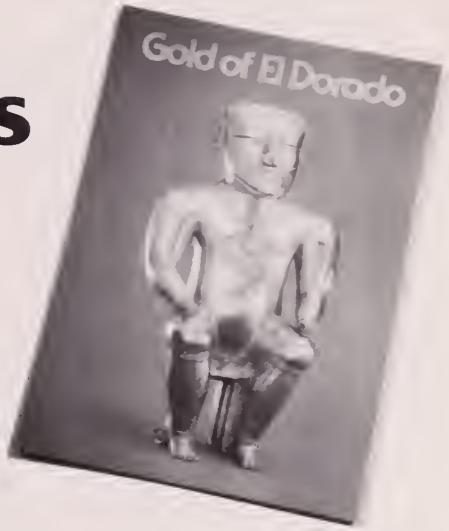
Piltdown in Letters

The role of the famous priest in the infamous conspiracy is here disputed in epistolary fashion

by Stephen Jay Gould

In "This View of Life" for August 1980, a case was made for the active participation of the French priest and paleontologist Pierre Teilhard de Chardin in the fraud of Piltdown man. In the months following the publication of that column, Natural History *received many letters expressing a wide variety of views on this subject. Presented here are three letters in defense of Teilhard, along with a response from Stephen Jay Gould.* Natural History *welcomes additional letters on this scientific controversy.*

To the Editor:



From the moment of discovery, the Piltdown "fossils" were the center of controversy. Piltdown apparently provided a human fossil on English soil, a maker for the eoliths, and proof that the brain came first in human evolution and that an anatomically modern braincase was present at the beginning of the Ice Age. Every conclusion was important and controversial, and for many years it was not possible to discuss human evolution without considering Piltdown. Hundreds of papers were written about the discoveries, but the problem remained. Anatomically it seemed impossible to associate the skull and jaw, but the chance association of an ape's jaw and a human skull in England seemed at least as improbable. The solution came when J.S. Weiner, Kenneth Oakley, and W.E. le Gros Clark showed that everything was fake—the bones had been stained, ape's teeth filed down, and fossils added to the assemblage to determine the antiquity. The whole matter is carefully reviewed in Weiner's *The Piltdown Forgery* (1955).

Obviously, from the point of view of science, the importance of discovering the forgery was to remove the chimera, as Franz Weidenreich called it, from the list of human fossils. In my opinion, the great interest in Piltdown lies in why major scientists accepted it, not in who forged it. Uncertain conditions of discovery, lack of geological information, and virtual anatomical impossibility did not deter many scientists from giving Piltdown a key position in their theories. As Alěs Hrdlička remarked on Piltdown in *The Skeletal Remains of Early Man* (1930), "It is another case where a desire to reach conclusions from insufficient and problematical material has led to a cloud of speculation and opinion." Yet many scientists did take a very strong position for or against Piltdown. To many it was the most important fossil in proving the antiquity of anatomically modern human beings, and any doubts about Piltdown were treated as an attack on a whole way of looking at human evolution. Piltdown was a center of very strong national, personal, and technical biases, and I think it is very difficult for people today (when there are so many well-preserved and -dated fossils) to realize how much emotion was invested in theories based on very little information.

Proof of the forgery finished scientific interest in Piltdown, but the very human question remained: Who had done it? This is very carefully considered in Weiner's book, and the story is much too long to repeat here. The core of the matter is that three people were personally involved in the excavations—Charles Dawson, Arthur Smith Woodward, and Teilhard de Chardin. Dawson took the originally "discovered" bones to Smith Woodward, a distinguished scientist at the British Museum. Later, Smith Woodward took part in the excavations, but it is not thought that he was involved in the forgery. His account of Piltdown is given in *The Earliest Englishman* (1948).

Dawson not only made most of the finds, but was present when the others—Smith Woodward and Teilhard—made discoveries. Prior to Piltdown, Dawson had been accused of plagiarism, fakes, and "undoubted deceptions." The evidence against Dawson is summarized in Wilton M. Krogman's "The Planned Planting of Piltdown: Who? Why?" (*Human Evolution: Biosocial Perspectives*, edited by S.L. Washburn and E.R. McCown, 1978), and I think that it is generally believed that he was involved in the forgery. After Dawson's death, Mrs. Dawson sent some parts of human skulls from her husband's collection to the British Museum, and it turned out that these had been stained with the same chemicals used in the forgery. I will return to the matter of

An Art Book That Took Centuries To Create

It took the American Museum of Natural History four years to arrange its exceptional exhibition of more than 500 pieces of ancient gold from Colombia. But those few years are a brief time when compared with the decades archeologists have spent digging (literally!) and studying the gold artifacts from tombs, caves, and buried sites. And all that time is short when compared with the many centuries prehistoric Indians practiced their craftsmanship and artistry to create these treasures.

So when it became the United States sponsor for this outstanding collection, the American Museum faced a dilemma. Could we do justice to all this effort and scholarship and beauty? We think we have. First, by dramatically displaying *Gold of El Dorado: The Heritage of Colombia* in one of our largest halls. The glowing reports from visitors tell us our efforts have been worthwhile. If you don't have a chance to see the show for yourself in New York, we hope you will see it in Chicago, San Francisco, or New Orleans on its year and a half tour.

The second challenge for the American Museum was the creation of an appropriate book to accompany the exhibition. We decided against a traditional catalog; against a small, boring volume with tiny black-and-white pictures that could never do justice to these fine objects. Instead, we decided to present a select number of the finest pieces of pre-Columbian gold in a large, stunning format. And to represent the three important elements that make a great art book we chose outstanding professionals.

First, photographer Lee Boltin. One of the greatest photographers of art objects, he also took the famous pictures of the Tutankhamun show. We sent him abroad to find and record great pieces of pre-Columbian art.

Second, archeologist Warwick Bray, from the University of London. One of the world's foremost authorities on pre-Columbian art, Bray is also a skilled writer, able to present fascinating background in a succinct, readable essay in the book. Dr. Bray organized the Colombian gold exhibition in London.

Third, Harry N. Abrams, Inc., America's leading publisher of fine art books. In a co-publishing venture with the American Museum, Abrams designed the book, supervised the preparation of 30 large color plates, and monitored the fine-quality printing.

The result is an unprecedented exhibition book. It is bold and big—each plate is 16 by 11½ inches—bigger than this magazine *opened up*. The paper is heavier than most posters. In fact, many persons have purchased two copies of the book in order to have one set of these fine art prints for framing.

And now for the happy ending. Because the Museum is a co-publisher, we are able to offer this soft-bound art book at a major savings from its normal retail price of $12.50. We are pleased to offer *Gold of El Dorado* to subscribers for only $6.25—a 50% savings off its regular price. This special offer is valid only during the exhibition and only while our limited supply lasts. We suggest that you order one or more copies immediately. Of course, if you are not satisfied after you have had an opportunity to examine it in your home, simply return the book and the Museum will refund the purchase price.

the evidence against Dawson, but the question has been raised of whether he could have executed the whole forgery alone. Gould believes that there was a conspiracy, that Teilhard de Chardin was at the root of it, and that the evidence he presents is so powerful that "the burden of proof must now rest with those who hold Father Teilhard blameless."

When Piltdown was proven to be a forgery, I wrote to Teilhard asking him for a note for the *American Journal of Physical Anthropology* (I was editor at the time). He replied at once that he could not believe that any of the people with whom he had been associated was guilty and that he was sure some other explanation would be found. I think that this is what Teilhard really believed; he had taken no part in a forgery and could not believe that the friends with whom he had been associated had either. In a letter to Oakley (cited by Gould), Teilhard refers to the discovery as spoiling "one of my brightest and earliest paleontological memories."

I think that the view that Teilhard was fooled (along with hundreds of others, it might be added) is reasonable, and I will try to demonstrate that Gould's view is almost certainly wrong. However, it is important to remember that the Piltdown events took place before World War I, long, long ago. Dawson died in 1916, Smith Woodward in 1944. There are few facts, and little chance of obtaining more hard evidence after all these years.

Gould believes that the motivation for the original fraud was a joke. Gould writes, "I assume that Piltdown was merely a delicious joke for him—at first," and continues with his fantasy of Teilhard's motivations, his desire, his envy, his trickery. Not only are there no facts whatever to support these allegations, but they appear to reflect Gould's own mental processes far more than those of Teilhard. On his reconstruction of Teilhard's motivation, Gould writes, "Here I see no great problem. . . ." I see nothing but problems in reconstructing the events and motivations of seventy years ago. Gould has given us a picture that distorts the few facts there are, and I think that his whole view of Teilhard is false. The following reconstruction is, I believe, more reasonable than the theory of the joke.

Here are my thoughts on what happened. They are not offered as facts, only as a possibility, and only because indirect evidence is being used to attack the reputation of a person long dead who cannot set the record straight.

As Gould states, "Dawson, of course, unearthed most of the material himself." The various "discoveries" were made over a period of four years —bones were stained, teeth ground, associated fossils and tools provided. When the issue arose of what a canine tooth in such a creature would be like, a canine was "found." When added proof was needed to show that the jaw belonged with the skull, Piltdown 2 was "found."

My bias is that the whole pattern of preparation of the teeth, bones, collection of associated "fossils" and the repeated releasing of strategic specimens was the result of deliberate forgery and could not have been a joke. The only individual consistently involved with all of the discoveries over all the years was Dawson. If it is accepted that Dawson was the forger, then Teilhard was either fooled or he was a forger too.

Could the original discovery have been the joke, planted by Teilhard and found by Dawson? Even if we forget the elaborate nature of the preparation of the specimens, the staining of the first "find" and of the bones sent by Mrs. Dawson to the British Museum is the same. Further, the canine tooth may come from the original jaw. The events are not independent, so that some might have been jokes and other fakes.

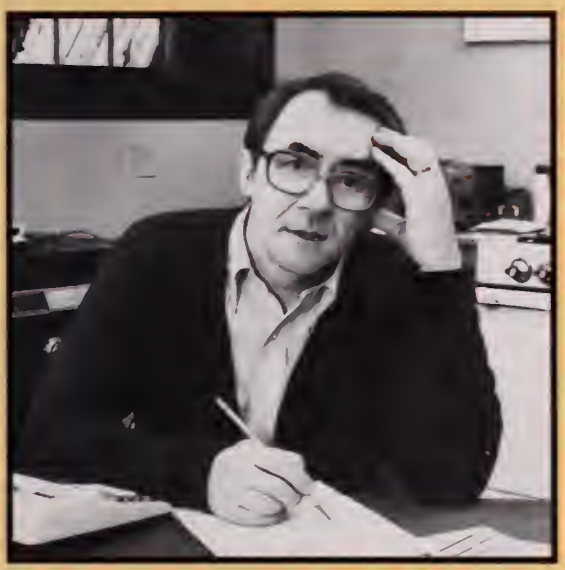
If the joke theory is out because of the difficulties of secretly collecting the specimens, preparing them, and arranging for their discovery, what was the motive for the forgery? Dawson gained worldwide recognition for his finding of a fossil man. He reduced the chances of the truth being discovered (after giving the original "finds" to Smith Woodward) by having a distinguished scientist (Smith Woodward) and a friendly young priest (Teilhard) make additional discoveries.

In retrospect the motivations and methods seem clear. Teilhard enjoyed his friendship with Dawson and the excitement of the discoveries. It was an honor for him to be associated with Smith Woodward. He had nothing to gain by being a secret conspirator, and if he had been one, he risked everything—his reputation as a priest and as a scientist.

I think it reasonable to interpret the events in this way, but whatever the truth may have been, it should be noted that all the events took place before Dawson's death in 1916—no Piltdown fossils were ever found after that although searches were made.

Gould cites no direct evidence against Teilhard; his account simply puts all events in the worst possible light. He argues that the forger would not have dared to put the carefully prepared canine in the gravel pit for fear of it being lost rather than discovered. By implication one of the forgers found the canine. Nonsense. The tooth could have been put where it almost surely would have been found or easily retrieved for a second try.

On Piltdown 2, Gould makes much of the dates. Teilhard must have seen it in 1913, but the "find" was not announced until 1915. Dawson's reasons for not announcing it sooner involve Dawson's motivations, not Teilhard's. Teilhard was in the French army. To be shown a fake does not make a person a faker.



Teilhard thought that the jaw did not belong with the skull; many other scientists thought the same. The problem of the human joint and the missing condyle was pointed out immediately after the discoveries were described.

In 1915 G. Miller wrote, "*Deliberate malice* [emphasis mine] could hardly have been more successful than the hazards of deposition in so breaking the fossils as to give free scope to individual judgment in fitting the parts together." Note how close this is to the phrase "as if on purpose" that Gould finds so revealing. Miller cited nearly seventy references on Piltdown, and Teilhard offered no new suggestions on the relation of jaw and skull or condyle and jaw.

Gould makes much of the fact that he thinks Teilhard should have devoted more attention to Piltdown and that he did not because of his feeling of guilt. A different explanation is that Piltdown was a matter of intense controversy from the beginning. Perhaps his position with the church made Teilhard wary of becoming involved in futile, acrimonious controversy. His main interests were not at the level of debates on a single fossil but on a general philosophy of man. Teilhard had enjoyed making the discoveries and his friendship with Dawson and Smith Woodward, but he had no desire to enter into the Piltdown debate. This cannot be proved, of course, but I think Teilhard's actions are easy to

Some people feel...

"My house was robbed. My neighbor says I should 'pad' my insurance claim. Why should I have to lie to come out even?"

That's why we want you to know...

You don't have to lie to come out even. Your neighbor, like some homeowners, may be confused about what homeowners insurance actually provides for loss of contents. Some think it guarantees "replacement value." In fact, most homeowners insurance policies provide "cash value."

There is an important difference. "Replacement value" means the actual cost to replace—brand new—the stolen item. "Cash value" means the current *depreciated* amount the item was worth *at the time of* the loss.

For example, if your stereo is stolen, a standard homeowners policy would give you the "cash value." Assume you paid $1,000 for the stereo ten years ago; today it may be worth $500. So you would get $500 from your insurance company, minus the deductible you have selected.

Policies are available that offer "replacement value" or "agreed value." But, of course, these kinds of coverage are more expensive than the conventional homeowners policy. Which kind of coverage is right for you? Most people opt for the conventional homeowners policy. In the event of a major disaster, like a fire or a windstorm, it enables you to put your home together again. And in the event of a burglary, it will give you the fair "cash value" of the item you lost.

For more information, consult your insurance agent. Review your present coverage and ask about the kind of protection you feel you need. Determine costs. Check to see if your standard homeowners policy provides limited coverage on items such as paintings, prints, cameras, jewelry, silverware, or furs. If so, you may want additional coverage, or "floaters," for those valuables.

A frank talk with your agent can prevent surprises and create a better understanding of what you can reasonably expect from your insurance policy when you have a claim.

We're working to keep insurance affordable.

This message presented by the **American Insurance Association,** 85 John Street. NY. NY 10038

understand and certainly not proof of guilt.

Later, after the fake was exposed, Gould regards Teilhard's attempt to find explanation in the letters to Oakley as incomprehensible. But there is no problem if one thinks that Teilhard really believed his friends and associates of many years before were innocent. Why should he welcome the news that Dawson was a forger and that both he and Smith Woodward were dupes?

In instance after instance, an action or statement by Teilhard is taken to reflect guilt. For example, upon seeing the exhibit of the forgery at the British Museum, Teilhard is described as walking through "glumly." But an honest person seeing an exhibit that showed he had been hoaxed by a person he considered a friend might indeed feel glum.

Throughout the paper a misleading vocabulary is used—on page 14 Nixon is mentioned, and then on page 16 Teilhard is accused of "stonewalling." On page 14 Teilhard is described as hiding his real nature "behind a garb of piety." He did not "spontaneously" congratulate Oakley as "all other scientists" had. Reading this the unwary are likely to forget that the other scientists who took part in the excavations at Piltdown were dead.

There will, of course, always be uncertainty about the events and motivations of long ago. I happen to think that Teilhard was a sincere and honest human being, and that this accounts for the facts better than the idea that he was a forger. The joke theory just does not cover the facts at all.

In summary, one way of looking at the Piltdown forgery is that it started as a joke played by Teilhard de Chardin and that for the rest of his life he regretted it, but events had gone too far, and he did not have the courage to confess.

A different way of interpreting the same facts is that Piltdown was an elaborate and deliberate forgery, and that Teilhard was fooled, having trusted both Smith Woodward and Dawson. He expressed himself clearly on Piltdown, but avoided the bitter controversy as far as possible. He died a few months after the fake was discovered, still hoping that some other explanation might be found.

S.L. Washburn
Professor of Anthropology and University Professor Emeritus
University of California, Berkeley

To the Editor:

In reviewing the Piltdown forgery, Gould considers that J.S. Weiner has virtually proven that Charles Dawson was guilty of forgery, but he is looking for a coconspirator. He mentions the anatomist Sir Grafton Elliot Smith and the geologist W.J. Sollas, but he dismisses them as "farfetched and devoid of reasonable evidence." He then turns to Pierre Teilhard de Chardin, and after an extensive review of circumstantial evidence, he concludes that "Teilhard was an active coconspirator with Dawson at Piltdown." As to motive, Gould finds that "we must recast Piltdown . . . as a joke that went too far, not as a malicious attempt to defraud."

Other authors have speculated on possible coconspirators at Piltdown. Just before Gould, three French scientists (M. Blanc, G. Chapouthier, and A. Danchin) published a review of scientific frauds, including Piltdown. They mention Teilhard in passing but give more attention to Smith and Sollas, to both of whom they ascribe professional jealousy of Sir Arthur Smith Woodward, keeper of geology at the British Museum and principal advocate of Piltdown. They are inclined to consider Sollas as the most probable candidate, largely on the testimony of J.A. Douglas, Sollas's longtime colleague and his successor in the Chair of Geology at Oxford. In his retirement on the Isle of Wight, Douglas discussed Piltdown with R.L.E. Ford, his neighbor and an amateur paleontologist. Douglas preferred not to make his views public out of deference to the family of his predecessor, but Ford persuaded him to put them on record before his death. As he was then blind, he made a tape that was played at a symposium at Reading after his death in 1978. L.B. Halstead published parts of the transcript with a commentary in *Nature*. He noted that it was generally felt that the coconspirator must have been someone with considerable expertise and with animosity toward Smith Woodward. Sollas satisfied these requirements (as Teilhard did not). He was a leader of British anthropology, far above Smith Woodward (a specialist on fossil fishes) and the keeper of anthropology, W.P. Pycraft (an ornithologist). That Sollas detested Smith Woodward was well known to Douglas from personal experience, for he had attempted to mediate between them and had failed miserably. As professor of geology and paleontology at Oxford, Sollas had easy access to all of the bones used in the forgery. Further, he had bought a supply of potassium bichromate, a substance that was not in use in his laboratory at the time, but which was used to stain the Piltdown bones. Finally, Sollas and his photographer Bayzand had deliberately tricked Smith Woodward with another hoax, the Sherborne horse's head, then exposed him when he accepted it as genuine. Why not victimize Smith Woodward with a greater hoax, one for which Sollas was strongly motivated and for which he was eminently well prepared to provide both materials and expertise. On the basis of these facts and of long association with him, Douglas believed that Sollas had conceived the hoax and enlisted Dawson as a coconspirator.

Blanc et al. refer to an earlier paper by Pierre Thuillier that appeared in *La Recherche*. This is a review of two books that had just been published: *The Piltdown Fraud*, by Ronald Millar, and *Pleine lumière sur l'imposture de Piltdown*, by Guy van Esbroeck. As I have not seen these books, the comments below are based on Thuillier's review. Millar found circumstantial evidence that convinced him that Smith was the culprit and that his motive was jealousy and a desire to ridicule Smith Woodward and Pycraft. Smith, an Australian anatomist, was professor of anatomy at Manchester and later at London. He too had the needed expertise and access to bones for the forgery. He mocked Dawson by telling him that the Piltdown fossils had been confirmed by similar finds at Pilton, Australia. This was pure fabrication: neither the town of Pilton nor the fossils exist. Clearly, Smith exploited Piltdown to bait his English colleagues. This infers that he knew that Piltdown was no more valid than Pilton. And how better to get that knowledge than from participation in the conspiracy? One must wonder whether Gould could have dismissed Sollas and Smith so lightly had he not been, in his own words, "too blinded by my own attraction to the hypothesis of Teilhard's complicity."

Van Esbroeck introduced yet another potential conspirator, William R. Butterfield, curator of the Hastings Museum, of which Dawson was a committee member. According to van Esbroeck, Butterfield was anxious to

NOW WE KNOW WHAT IT'S LIKE TO BE ALONE.

It wasn't always this way.
It used to be hard to decide among all the 35mm SLR's.
Then we created the new Minolta XG-M. A camera so extraordinary it stands alone in its class. With an unrivaled combination of creative features.

First, it's automatic. So it's easy to get sharp, clear pictures. You just point, focus, and shoot. It even has electronic features that keep you from making mistakes.

As your skills advance, you'll appreciate advanced features like metered manual and exposure override for full creative control.

To further separate ourselves from the competition, we built in the option of professional motor-drive. Something normally found only on more expensive cameras.

It lets you shoot a blazing 3.5 frames per second. So you can catch a baseball as it comes off the bat. Or halt a horse leaping a hurdle.

But to fully grasp the XG-M's advanced design, you have to hold it.

The body feels rugged yet light. With a built-in textured grip that's sculpted to fit snugly in your hand. And oversized controls that make it easy to adjust to changing conditions.

As your creative potential develops, you'll have access to over 45 interchangeable, computer-designed Minolta lenses. As well as the Minolta system of SLR accessories.

All in all, the XG-M is a remarkable achievement. But then, we have over 50 years of remarkable achievements to draw on.

The new Minolta XG-M. Now we know how it feels to be alone.
But we're not complaining.

WAIT 'TIL YOU SEE HOW GOOD YOU CAN BE.

have certain specimens that Dawson had given to the British Museum. He swore vengeance on both Dawson and Smith Woodward. According to this version, Butterfield planted the bones in an area in which Dawson was collecting, and he thus duped Dawson as well as the "experts" of the British Museum.

Gould summarizes his case against Teilhard inversely as follows: "First, perhaps Piltdown has simply deluded another gullible victim, this time myself. Maybe I have just encountered an incredible string of coincidences. Could all of the slips in the letters have been innocent errors of an aging man; the *comme par exprès* merely a literary device; the failure to use his best argument a simple oversight; his conspicuous silence beyond a few fleeting and unavoidable mentions only an aspect of a complex personality that no one has fathomed; the elephant and the hippo Dawson's property . . . ?" If each clause of that long sentence were recast as a positive statement, taken together they would constitute a good summary of the case against Teilhard. Let us therefore use the sentence as the basis for a brief rebuttal.

"Could all of the slips in the letters have been innocent errors of an aging man?" Yes, easily and probably. I am ten years younger than Teilhard was when those letters were written. I am still sufficiently alert to keep a jump or two ahead of my students. Nonetheless, I sometimes find myself uncertain of the sequence of events much more recent than those of which Teilhard was writing. When an error is called to my attention, I sometimes have to reconsider and mentally recast the sequence of events several times before I am confident that I have it right. One of Teilhard's favorite words was *tâtonnement* ("groping"). It describes well the process seen in his letters, a mental process that is common to many of us. Gould's writing has a ring of great self-assurance, and perhaps the need for *tâtonnement* is not apparent to him, but I believe that it is an adequate explanation for the inconsistencies in Teilhard's letters to Kenneth Oakley. Thus, Oakley's original hypothesis was probably correct.

In his 1920 article, in which he clearly states that the Piltdown fossils are a mixture of bones of two different animals, Teilhard says, "As if on purpose [*comme par exprès*], the condyle is missing!" Gould believes that Teilhard was trying, a bit too subtly, to tell his colleagues that Piltdown was a fraud and that the condyle had been deliberately broken off the mandible to make a test of articulation impossible. Gould acknowledges that *comme par exprès* may be just a literary device. Similarly, physicists and engineers, faced with bad results, speak of the perversity of inanimate nature, while biologists refer bad results to the "Harvard law," that under the most precisely controlled conditions an experimental organism does just as it pleases. Teilhard's writing is characterized by literary figures to an unusual degree: why not this means of expressing his disappointment that the defects of the fossils prevent a critical test? But there is also a third possibility. After his youthful and amateur enthusiasm had been dampened by the critical thinking of Marcellin Boule's laboratory, and after his paleontological acumen had there been raised to a professional level, he may have suspected that Piltdown was a forgery, and he may have intended to suggest by *comme par exprès* that possibly the fossils had been deliberately altered to prevent a critical test. Suspicion does not require complicity.

Teilhard emphasized that evolution was ordinarily divergent, with long, separated lines often appearing as multiple, parallel lines. This is simply adaptive radiation. Gould says that Piltdown should have been Teilhard's strongest argument for multiple, parallel lines in human evolution, and so he believes that Teilhard's failure to use it must have been caused by his guilt in the Piltdown conspiracy. But was Piltdown Teilhard's best argument, "the only available proof," as Gould says, "of multiple, parallel lineages within human evolution itself." Neanderthal man had been known since 1856, Cro-Magnon since 1868, and Galley Hill since 1888; *Homo erectus* had been known from Java since 1891 and was discovered in China in 1927 (by a team that included Teilhard), long before Teilhard wrote his most important works; and Heidelberg had been known since 1907. Other "parallels" discovered after Piltdown, but before Teilhard wrote the works upon which his fame rests, include Ehringsdorf (1925), Steinheim (1933), and Swanscombe (1935). One might also mention *Australopithecus* (1925), which has at times been assigned to the genus *Homo*. In the face of this array of fossils in the human lineage, could Gould cite Piltdown as "the only available proof" for Teilhard's thesis unless he were, in his own words, "too blinded by my own attraction to the hypothesis of Teilhard's complicity."

If we agree that Teilhard had abundant fossil evidence for his theory, one must still ask why he did not use Piltdown also. The answer is evident in his paper of 1920: he dissociated himself from the usual interpretation of the Piltdown fossils, and he may have suspected forgery. At best, therefore, its use was likely to lead to confusion; at worst, to totally erroneous conclusions. Having once stated his opinion on it fully, why not move on to more profitable materials? Much the same reasoning applies to "his conspicuous silence."

I believe that Gould's best argument is Teilhard's "profound embarrassment" when Oakley showed him the exhibit on the Piltdown fraud at the British Museum, and on other occasions when Piltdown was discussed. Nonetheless, it is understandable on grounds other than complicity. Teilhard's acquaintance with Dawson and Smith Woodward came in the days when he was an enthusiastic amateur with little hope of achieving professional status in paleontology. It may have been partly their influence that directed him toward a career in paleontology. He was characteristically intensely loyal to his friends and very slow to believe evil report about anyone. Thus the idea that his much admired friend Dawson, and perhaps others of the early Piltdown investigators, had deliberately defrauded the scientific community was distasteful in the extreme. He reacted with an embarrassed avoidance of the repugnant subject.

Because of Teilhard's experience at Cairo and his connections with the network of amateur collectors, Gould believes that he was likely to have obtained the elephant and hippo bones that were planted at Piltdown. Perhaps, but it should be added that Sollas, Smith, and Butterfield also had excellent access to networks of collectors, both professional and amateur.

Before summarizing, let me discuss a few minor points in Gould's article. At the outset, he refers to Teilhard as "one of the world's most famous theologians." On the contrary, he was not a theologian at all. Of course, he had studied theology as a seminarian.

The greatest exhibition of Shakespeare ever to travel is now at the American Museum of Natural History.

Enjoy the elegance of Elizabethan England in a unique display of memorabilia.

Experience the color and pageantry of court, country and city life.

See original 19th-century costume sketches from the Bard's most magical comedy.

Recapture performances of the world's finest actors in Shakespearean roles.

View the portrait of Shakespeare on the title page of the 1623 First Folio.

Relive the moments of history that Shakespeare chose to immortalize.

Imagine yourself at the theatre in this famous model of the London Globe.

Engrave this 1618 etching of Henry V in your memory.

Get thee to the exhibition!

June 18 through September 20

(The American Museum of Natural History–Central Park West at 79th St.)

Shakespeare: The Globe & The World is an exhibition from the collection of the Folger Shakespeare Library, Washington, D.C. Made possible by grants from the National Endowment for the Humanities, Metropolitan Life Insurance Company, Exxon Corporation and the Corporation for Public Broadcasting.

Similarly, all biologists study some chemistry, physics, and mathematics, but that does not make us chemists, physicists, or mathematicians. It is a common mistake to equate "priest" and "theologian." Later, Gould says that Teilhard "seemed to hide passion, mystery, and good humor behind a garb of piety." This seems to suggest hypocrisy, and I believe that it is not only unjustified but that it contradicts those who worked with him most closely (for example, George B. Barbour and Helmut de Terra).

Teilhard wrote to Oakley that, as a theology student at Hastings, he had not had much free time. Gould finds this inconsistent with Teilhard's letters to his parents, in which he talked much about travels in southern England. Again, it appears that the conflict is in the interpretation rather than in the facts. Anyone who knows anything about the Jesuit seminary curriculum knows that it is an onerous one that leaves minimal spare time. Nonetheless, there is always some time for recreation. When students write home, they rarely send transcripts of class notes. They are more likely to write about recreation, hobbies, and special interests, even if these occupy only a small part of their time.

Gould says that "Leakey also mentioned Teilhard's knowledge of chemistry and the clever staining of the Piltdown bones." Was his knowledge of chemistry out of the ordinary? He did no graduate work in chemistry. The main evidence of his expertise in this field is that he taught elementary chemistry for three years at the Jesuit college in Cairo. To teach elementary chemistry in a classical college, however, does not require any unusual mastery of the subject. Most of the principals in the case, as science graduates of British universities, probably equalled or surpassed Teilhard in this respect.

Let me summarize the case as I see it. Teilhard went to England as a seminarian with a strong extracurricular interest in natural history, especially geology and paleontology, and he put as much time into his hobby as the curriculum would permit. He soon met other amateur collectors, including Dawson, a lawyer who had been collecting in Sussex for many years and who had sent enough materials to the British Museum to make up a "Dawson collection." Teilhard was much impressed by his new friend and probably flattered that so senior and distinguished a collector should take an interest in him. When Dawson confided that he had found probable fossils of very early man, and especially when so distinguished a scientist as Smith Woodward championed the fossils, it could not fail to make a tremendous impression on a young amateur who had only dreamed of finding important fossils of early man and of receiving the confidence of scientists of the importance of Smith Woodward. In such a situation, it is hardly surprising that he was overawed, tended to romanticize the incident, and accepted it as presented by Dawson and Smith Woodward.

Upon returning to Paris, he began his work under Boule. Here, for the first time, he studied mammalian, primate, and human fossils systematically, and he learned the critical attitude toward them that was so characteristic of Boule. Here he became convinced of the incompatibility of the Piltdown jaw and cranium. At best, these now appeared as an accidental association of unrelated parts; at worst—could it have been fraud? Possibly he was suggesting this very tentatively with the phrase *comme par exprès*. He shrank from the repugnant possibility that any of his friends might have been involved in such an act. In any event, having once called it right (1920), he then put it out of mind and went on to other materials that did not raise such distressing problems.

When, forty years after the events, Oakley questioned Teilhard, it is hardly surprising that he had to grope for the answers. Far from suggesting complicity (as it might, had it concerned recent events), it merely suggests that, for all the sublimity of his thought, he was still very much a man with human limitations, even as the rest of us.

After all of this, I must concede that it is possible that Gould is right, although I do not consider it probable. If so, his hypothesis of a joke that got out of hand seems to be the best available explanation. The French love to twist the tail of the British lion, and Teilhard was a quintessential Frenchman.

But if not Teilhard, then who? Smith and Sollas are implicated far more strongly than Gould concedes. On the basis of Douglas's statement, I would consider Sollas to be the most probable coconspirator. As I have not seen van Esbroeck's book I cannot assess

the probability of Butterfield's complicity, but neither can I dismiss it out of hand. Finally Weiner mentions several other people who, in various ways, were associated with the Piltdown finds. Among these, I select for mention Sam Woodhead, a chemist friend of Dawson's, and Lewis Abbott, a competing collector who had a strong dislike for Dawson. Thus, a considerable number of potential coconspirators are in the field. And we must not overlook the possibility that there may have been three or more conspirators at Piltdown.

The late W.R. Brooks, founding chairman of the Department of Biology at John Hopkins, said that "suspended judgment is the greatest triumph of intellectual discipline." Until definitive evidence is available, we should aspire to that triumph in regard to the Piltdown conspiracy.

Edward O. Dodson
Department of Biology
University of Ottawa

To the Editor:

Many years ago I referred in a lecture to the Piltdown forgery. Subsequently I was admonished by two angry British dentists. "An Englishman would never do such a thing, but don't forget, one tooth had been found by a French Jesuit."

In this magazine for August 1980, there appeared an article by Stephen Jay Gould trying to prove that Father Teilhard de Chardin had knowingly been involved in the Piltdown fraud. Gould is as positive in his interpretations and conclusions as he is wrong, and his article cannot be accepted without protest and correction.

It is not necessary here to repeat the story of "Piltdown man," which turned out to be a chimera, a composition of a hominid braincase and the mandible of an ape. Irritating from the beginning, this find had troubled a whole generation of earnest scientists. Teilhard, then a young and inexperienced man, had contact with Charles Dawson, the alledged discoverer, and participated on occasion in his fieldwork. This makes Teilhard part of the Piltdown story. The other person involved was Sir Arthur Smith Woodward of the British Museum, a scholar of considerable reputation.

Dawson had long been suspected to be the perpetrator of Piltdown man. But there was no proof of this. In a painstaking, thoroughly convincing way, Kenneth Oakley and J.S. Weiner

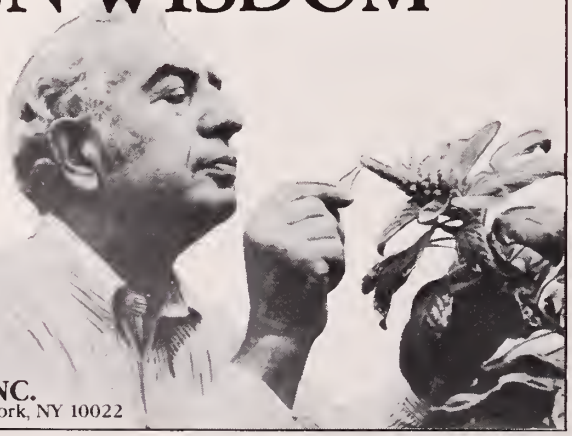
showed that the skeletal remains were modern and not of Lower Pleistocene age as alleged; that the bones and implements had been artificially stained to suggest fossilization; that the teeth of the mandible had been filed; and that the mammalian fossils had come from elsewhere. Every bit of "evidence" pointed to Dawson. Yet, at the end of his book Weiner hesitated to come to a definite conclusion. None of the facts presented in his book "furnishes the positive and final proof of [Dawson's] responsibility." Was this just fairness against a deceased man, or was Weiner afraid to get into trouble with the Dawson family? After all, Dawson's son was a prominent government official. More important was Sir Arthur, the grand old man who had followed the Piltdown story from the beginning and had known everybody involved. Shortly before he died, Sir Arthur stated that information furnished him by Weiner "left me no doubt that the man I had the greatest reverence for [Dawson] *had deliberately misled his best friend,* who stood rather outside the Piltdown discovery" (*Sunday Times*, January 9, 1955).

Dawson was a solicitor and a roving amateur in many ways. But did he have the intelligence to plan the complicated forgery himself? From where did he get the material? What motivated him?

It has long been suspected that there must have been a trained scientific man behind Dawson. The Piltdown mystery must have been a conspiracy. Yet who was the second man, the perpetrator, the shadow figure in the background? Two were named in this connection: Grafton Elliot Smith and Teilhard de Chardin. Ronald Millar, not convincingly, tried to put the blame on Smith. Now Gould bluntly accuses Teilhard de Chardin.



In this article Gould uses every bit of information, every uncertainty in the record, every dubious attitude of Teilhard's as evidence of his complicity. In 1953, Teilhard's recollection of what had happened before the First World War was really so uncertain that he thought of having met Dawson for the first time in 1911 while actually it had been in 1909. Had this (according to Gould) been written on purpose, or had Teilhard just "misunderstood the exact chronology"? When later on, "Teilhard's silence about Piltdown becomes inexplicable to the point of perversity (unless guilt and knowledge of fraud engendered

Unlocking the secrets of plants

One of America's leading botanists, the author of a popular column in *Natural History* magazine, provides a revealing look at "green wisdom"—the remarkable behavioral strategies built into plants. Through a series of vividly written vignettes, the author gives "a lucid account of how plants of all sizes manage to overcome challenges and prosper. But GREEN WISDOM does more than provide entertaining information. It gives the reader a chance to see in each example of plant life a pattern that can be applied by imagination to the improvement and enrichment of human life."—Rene Dubos

it)," then the perversity is Gould's. Might he not have thought of another explanation more in accord with Teilhard's great reputation as an honest scientist? That, conceivably, insight and experience were behind Teilhard's attitude?

In 1929 Teilhard went to Peking just in time to become involved in the discovery of Peking man. He could study the remains prior to publication and discuss the question of human evolution and Piltdown man with Davidson Black and later with his successor, Franz Weidenreich. The latter gave an outspoken verdict about Piltdown. He, in 1932, proved the mandible to be that of an orang; Friederichs, one of his pupils, even suggested a special genus of anthropoids for that find—*Boreopithecus*. Already earlier G. Miller, in 1915, had thought the jaw belonged to a chimpanzee, and so did others, such as Remström (1916), Gregory (1916), and Lonshossek (1920).

That the Piltdown mandible belongs to an ape, and the canine he found as well, must have been a personal blow for Teilhard because he had found the canine, in August 1913, "in the rain-washed gravel spread" on the surface, while at the same time Dawson and Smith Woodward were excavating nearby. Therefore, Dawson was around, and knowing the history of the finds (Weiner) there could be no doubt that Dawson must have "planted" the tooth on purpose, ultimately to be discovered by Teilhard. It was this find by which Teilhard was inadvertently dragged into the Piltdown fraud.

Teilhard had ample knowledge of the Pleistocene fauna and naturally must have known that a Pleistocene ape could for climatological and ecological reasons not have existed in Europe. Therefore, he must have felt deceived and cheated. He loathed, no doubt, to suspect anybody and did not want to have anything to do with the case. After the forgery had been disclosed and a special exhibition had been presented by the British Museum, Teilhard did not even want to look at it. He had had enough of Piltdown. This, in contrast to Gould, is my explanation of Teilhard's changed attitude in the Piltdown case.

About the alleged stone implement, Gould writes, "I also have some doubt about Teilhard's flint, for it is the only Piltdown item indubitably found *in situ*. Now, if we look into Weiner's

book, we find, "The paleolith flint (nr. E. 606), however, provided a notable exception . . . this was found in situ by Teilhard de Chardin. . . . But that this fragment has been deliberately stained admits of no doubt." The person who had stained the bones also had stained the flint. For details one might look up Weiner's book, which actually reads like a detective story. The implement must have been placed at the site with the purpose of deceiving Teilhard and this could, in view of the former suppositions, only have been done by Dawson.

Gould's suggestion that Teilhard was presumably an ardent French patriot is noteworthy: "what a wonderful joke for a Frenchman . . . what an irresistible idea to salt English soil with this preposterous combination of a human skull and an ape's jaw and see what the pros could make of it." What an incredible insinuation against an honest scholar!

Gould's article is based entirely on speculations. Could it really satisfy anybody to maintain that "Teilhard was an active collaborator" of Dawson's alleged conspiracy? "Only in this way," according to Gould, "can I make sense of the pattern in Teilhard's letters to Oakley, the 1920 article, the subsequent silence, the intense embarrassment."

Who then was the mastermind behind Dawson, and what was the motive? The oldest prehistoric man an Englishman? National pride or perhaps the reward of becoming a fellow of the Royal Society?

At long last, by an event as surprising as it was unexpected, we are able to present a reasonable explanation. The person responsible for the fraud was Professor W. J. Sollas of Oxford. The late Professor J. A. Douglas (1884–1978), who held the Chair of Geology at Oxford and was a close friend of Sollas, had known the truth. Shortly before his death, Douglas transmitted the story by tape recording. He had a "bitter dislike of Smith Woodward, which was mutual." He wanted to make a fool of him, to ruin his scientific reputation. And this led to the Piltdown forgery. (As reported by B. Halstead in *Nature,* vol. 276, pages 11–13.) It is a pity that this revelation should have been overlooked by Gould. Otherwise his concoctions would never have been printed.

As for Teilhard's alleged "guilt," it is quite evident that he was but an interested yet innocent bystander

of the Piltdown case, who had the misfortune to pick up the canine tooth and the flint, *in situ* at the site where the shameful forgery was committed.

G. H. R. von Koenigswald
Department of Paleoanthropology
Senckenberg Museum
Frankfort/Main B.D.

Stephen Jay Gould replies:

I began my first article on Piltdown (*Natural History*, March 1979) with the words: "Nothing is quite so fascinating as a well-aged mystery." Thus, I cannot feign a scholar's surprise and claim astonishment at either the volume or the vehemence of correspondence provoked by my case for Teilhard de Chardin as a coconspirator in the most celebrated of anthropological forgeries (*Natural History*, August 1980).

I was pleased by the favorable reaction of most correspondents, especially by the recognition of so many that my case was not born of malice toward Teilhard. For if I have emphasized any theme over eight years of these columns, it is the human side of science and its embeddedness in social contexts. If I am right, I do not see how Teilhard's greatness is diminished by a youthful caper that caused him continual pain thereafter. A tragedy provoked without malicious intent by one's own hand is perhaps the most poignant burden that anyone can bear. As a Jesuit priest wrote to me: "I do not know if you are right, but the spirit of your argument commands respect. After all, our church maintains the institution of confession because we know that people err—even priests."

Favorable respondents write short notes or pass a friendly oral remark. Long commentaries—quite appropriately—are the domain of critics. I merely wanted to say that the three published here are not the tip of an iceberg of discontent, or, if they are, the iceberg of good cheer is at least as large if not so heavy.

In these three commentaries, Teilhard's friends and supporters react. Professor Dodson spent a sabbatical year at the Fondation Teilhard de Chardin in Paris. Professors Washburn and von Koenigswald, two of the most eminent physical anthropologists of our century, were friends and colleagues of Teilhard. Their covering letters express an anger not found—and I thank them for it—in their actual responses. I am neither sorry nor

surprised by these commentaries, although I am disappointed in one sense (and secretly pleased in another) by their weakness based upon a common failure to state accurately or even to consider the major points of my case. (My pleasure, of course, derives from the survival, if not strengthening, of my hypothesis in the face of criticism from its potentially most severe and knowledgeable critics.)

A standard method of attack against complex hypotheses involves chipping away at unimportant and admittedly weak points, ignoring the strong points, and then hoping that the edifice might tumble by implication. Because I anticipated such a response, I was careful to list my arguments explicitly in the order of their strength as I saw it. I even numbered them and stated that the first two were my essential claims, and all the others subsidiary. Yet both Washburn and Dodson devote most of their responses to the subsidiary points.

The first two-thirds of Washburn's commentary is primarily an argument for Dawson's involvement in pursuit of fame. I disagree with none of this and find most of it irrelevant to my case. Washburn seems to be under the misconception that I tried either to exonerate Dawson or to paint Teilhard as the mastermind and Dawson as the tagalong. On the contrary, I clearly stated my assumption of Dawson's guilt on the first page: "J. S. Weiner's elegant case virtually precludes Dawson's innocence." On the same page I wrote that Dawson had "found" the initial bones before Teilhard arrived at Piltdown and that he must therefore have been the chief perpetrator of the hoax. The only possible relevance of the first two-thirds of Washburn's letter relates weakly to my speculations about Teilhard's motive (a theme that I regarded as the least important of my piece and therefore relegated to the last page —we can only speculate about motives, but we can present facts about involvement). Washburn argues that if Dawson was a forger and if Dawson acted maliciously for fame, then Teilhard was either innocent or also acted from malice (and not for a joke, as I speculated). But how does this follow? If we know anything about conspiracies in all their murkiness, we certainly understand that people get involved in common projects for the damnedest and most varied motives. Do any of the Kennedy assassination

buffs believe that Oswald, Ruby, and the masterminds undertook their deeds for common reasons?

When Washburn does reach my specific arguments, he begins with my very last point, Teilhard's "good luck" in finding the canine tooth, of which I stated: "It is the weakest point of all, hence its place at the bottom of my list."

Dodson proceeds in much the same way. For example, he attempts to demolish what he takes to be one of my strong points in almost the very words I used in labeling it a weak point. To the argument that Teilhard might have supplied African elephant and Maltese hippo teeth to the "associated fauna" at Piltdown, Dodson writes: "Perhaps, but it should be added that Sollas, Smith, and Butterfield also had excellent access to networks of collectors, both professional and amateur." I wrote, labeling the point as my next to weakest: "I regard this argument as suggestive, but not compelling. Dawson too was plugged into a network of amateur exchange." Dodson then spends a paragraph attacking Leakey's point that Teilhard taught high school chemistry in Egypt and may therefore have known how to stain the bones. But I regarded this argument as so by-the-by that I didn't include it in my list at all.

When the three commentators do consider my two major points, they either state them incorrectly, or so incompletely that my arguments are unfairly represented and converted to straw men. Let me then rehearse the two foundations of my case and comment upon the attempted rebuttals:

1. Teilhard wrote a series of letters to Kenneth Oakley in 1953. In the first, he slipped (fatally, I believe) in stating that Dawson had shown him the site of the second Piltdown find and explained to him that he "had found the isolated molar and the small piece of skull in the heaps of rubble and pebbles raked at the surface of the field." This is impossible because Dawson "found" the bones in 1915 and Teilhard was sent to the front in December, 1914. If Teilhard saw the Piltdown 2 material, he probably helped Dawson to manufacture it before he left. Oakley caught the inconsistency immediately and pressed Teilhard. Teilhard's subsequent letters contain what I take to be a studied retreat surrounded with a set of other misstatements or half statements, all forming a pattern, carefully constructed, in my opinion, to suggest innocence and avert suspicion. In my article, I placed primary emphasis upon the *pattern* of misstatement. I acknowledged that each individual point could be given an exonerating interpretation, but that my case resided in the common pattern of all misstatements—"each insignificant (or subject to other interpretations) by itself, but forming in their ensemble a subtle attempt to direct suspicion away from himself."

Washburn devotes but one short paragraph to this essence of my case, says nothing about my claim for pattern, and dismisses my central point about the Piltdown 2 specimens by stating: "To be shown a fake does not make a person a faker." I agree, but I explicitly discussed this possibility and gave my argument against it. I framed Washburn's claim as follows: "Dawson showed the specimens to an innocent Teilhard in 1913, but withheld them from Smith Woodward

The Soligor 80-200mm Expand Your Horizons By Getting Close.

You've got a terrific 35mm SLR camera, but not all of your shots are terrific. Some suffer from too much unwanted scenery, some from tiny people in big frames...shots that didn't work because your creative I.Q. was more than your *lens* could handle.

That's right, lens. But, Soligor has a solution: the affordable, innovative Soligor 80-200mm One-Touch Zoom + Macro lens that lets you and your camera turn blah into beauty.

Zoom in to crop out extraneous details. Bring your subjects up to 4 times closer than a standard lens can. Frame your shots exactly as you want them, and Soligor quality captures them faithfully. Create exciting portraits, instead of just pictures of people; capture a still life or sports action as the kind of picture you bought your camera to get; experiment with amazing close-ups, thanks to macro ability. And it's all so easy with Soligor's single One-Touch control for zoom, focus and macro.

If some of the zip has gone out of your picture taking, zip down to your Soligor dealer and try our 80-200mm on your Canon, Minolta, Pentax, Olympus, Nikon or other fine camera. Or, write for full information.

until 1915." I then responded to this potential interpretation:

> Dawson would not blow his cover in such a crude way. For Dawson took Smith Woodward to the second site on several prospecting trips in 1914, always finding nothing. Now Teilhard and Smith Woodward were also fairly close. Dawson had introduced them in 1909 by sending to London some important mammal specimens (having nothing to do with Piltdown) that Teilhard had collected. Smith Woodward was delighted with Teilhard's work and praised him lavishly in a publication. He accepted Teilhard as the only other member of their initial collecting trips at Piltdown. Moreover, Teilhard was a house guest of the Smith Woodwards when he visited London in September 1913, following his discovery of the canine. If Dawson had shown Teilhard the Piltdown 2 finds in 1913, then led Smith Woodward extensively astray during several field trips in 1914, and if an innocent Teilhard had told Smith Woodward about the specimens (and I can't imagine why he would have held back), then Dawson would have been exposed.

Dodson also grants my central point but a single paragraph, says nothing at all about the inconsistency in dates for Piltdown 2, and argues only that the series of slips should be seen as a *tâtonnement*, or "groping," on Teilhard's part. Dodson merely asserts this interpretation without mentioning the details of a single slip and without even acknowledging my central claim that all the slips have a common theme and thus cannot represent, in my view, a groping to remember the truth.

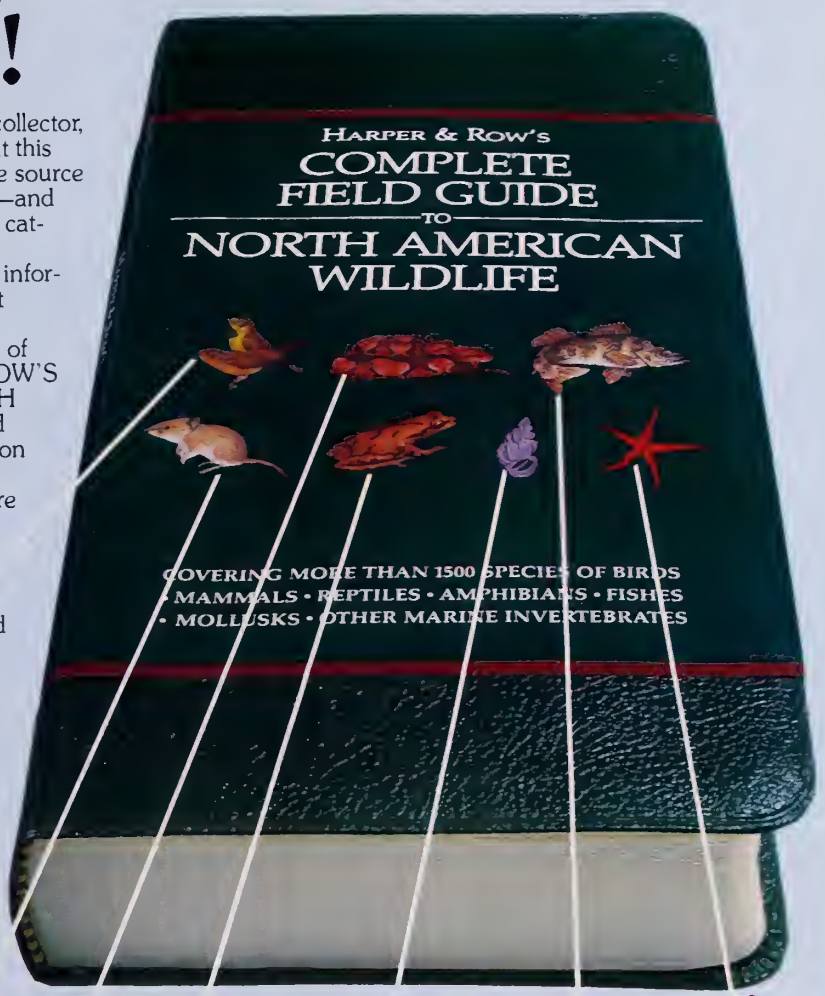
Von Koenigswald, also treating my central point in one paragraph, ignores the chronological problems of Piltdown 2. (Thus, only one commentator in three even deigns to mention my single strongest argument.) He uses one of Teilhard's subsidiary slips (misstating the year he met Dawson) as evidence of his general forgetfulness, again not acknowledging my claim that all the errors form a pattern, whereas general failure of memory should not yield order. By the way, Professor von Koenigswald is mistaken in stating that Teilhard was "inadvertently dragged into the Piltdown fraud" when he discovered the canine in 1913. Teilhard accompanied Dawson and Smith Woodward during their very first excavation together in 1912. In fact, Smith Woodward had requested that Dawson include no locals in the work, and Dawson had permitted only Teilhard to accompany them, declaring to Smith Woodward that the young priest was "quite safe."

2. Teilhard's silence. Teilhard wrote one short article on Piltdown for a popular journal in 1920, correctly stated that the skull and jaw belonged to two separate creatures, and then proceeded to avoid the subject for the rest of his career. It is the profundity of his silence that I find so startling. Through twenty volumes of collected works, I can find only half a dozen incidental references, either an item in a list, a dot on a graph, or a mention in a footnote—never so much as a single sentence. Yet, as I argued, the Piltdown skull (which, if he was innocent, should have remained a genuine human fossil in his eyes, even if he attributed the jaw to an ape) represented his best argument for a central claim in his evolutionary philosophy—multiple, parallel lineages striving upward toward the domination of matter by spirit. Why did he not use it? He wrote volumes on the legitimate Peking man and at least four review articles on human evolution in general. These articles treat dubious and fragmentary remains, of which Teilhard had no personal knowledge, in detail. Why did he leave Piltdown out if he believed the skull to be genuine?

Since writing my article, I have learned of another small point that makes the silence even more puzzling. When Peking man was discovered, its cranium was reconstructed incorrectly to yield a capacity lying, like Piltdown's, in the modern human range. This unleashed a volume of commentary about the relationship between Piltdown and Peking. Now Teilhard was in China and was contributing (as a geologist) to the original Peking finds. He was the only one there with personal knowledge of Piltdown. Yet, so far as I can tell, he said nothing at all. His own mentor, Marcellin Boule, published a paper comparing the Peking and Piltdown craniums. It included long quotations from Teilhard about the geology of the Peking site, but not a word from him about the craniums.

Washburn again gives this second major claim but a single paragraph, presenting two implausible alternative suggestions to explain Teilhard's silence. First, he conjectures that Teilhard's precarious position with the church may have led him to avoid the controversy. But if Teilhard was playing it safe, why did he write, and circulate extensively in samizdat, the many volumes that the church truly regarded as heretical and enjoined him from publishing—the posthumously printed works that made him a cult figure after his death? Second, Washburn conjectures that Teilhard simply wasn't interested in Piltdown and debates about single fossils, but in a "general philosophy of man." But this makes no sense for two reasons. As I stated above, Piltdown was Teilhard's best empirical argument for this "general philosophy," and he never used it. And if he had so little interest in single fossils, why did he write volumes about Peking man and many review articles about the empirical data of human paleontology—including all the other dubious and problematical fossils. Teilhard was not a man who avoided controversy.

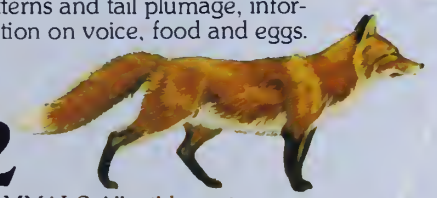
Dodson at least gives my point some space and consideration. He mentions a suite of other human fossils to counter my claim that Piltdown was Teilhard's strongest argument for multiple, parallel lineages. But all these other fossils are consistent with a unilinear phylogeny of *Pithecanthropus*–Neanderthal–modern humans, and many of Teilhard's contemporaries arranged them in just such a scheme (others considered Neanderthal as a side branch). Piltdown was the one clear demonstration of *multiple* lineages, for Piltdown, with its modern skull (literally, as we now know), was the contemporary of big-jawed, beetle-browed Neanderthal.



Dodson's alternative explanation for Teilhard's silence is reasonable and I considered it in my article—that Teilhard knew Piltdown was a fake but did not participate in the forgery himself. I agree that Teilhard's extraordinary silence only demonstrates his knowledge or strong suspicion of forgery, not his participation in it. But this is why my case is multifaceted. The silence indicates his knowledge of fraud; had I found this alone, I would not have implicated him directly. It is my other finding—the pattern of slips and later evasions in the letters to Oakley—that seems to me best explained as Teilhard's attempt to cover up an actual involvement. For if he were innocent and only suspicious, why the telling slip in the dating of Piltdown 2 and why a pattern of errors and evasions that seems designed to divert a consideration of his own possible role?

According to von Koenigswald,

NEW: You'd need 7 separate field guides to get all the information in this one!

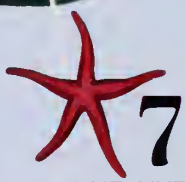


Whether you're a bird watcher, a shell collector, or any lover of the outdoors, you'll want this book with you on every trip. It's the one source on all the commonly observed species—and many of the rare ones—in seven major categories. And for all its completeness, its abundant illustrations and fully detailed information, it's still compact and lightweight enough for your jacket pocket.

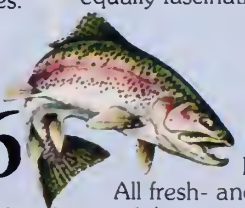
Compiled under the supervision of distinguished zoologists, HARPER & ROW'S COMPLETE FIELD GUIDE TO NORTH AMERICAN WILDLIFE is designed and organized for quick and sure identification of species. Its more than 2,000 illustrations by leading natural history artists are carefully painted and printed to reveal key features and true colors. Its sturdy binding, strong bible paper and waterproof vinyl cover make it a rugged as well as a fascinating companion for field or forest, desert, mountain or shore.

1 BIRDS are shown in all their diverse plumages, with close-ups of flight patterns and tail plumage, information on voice, food and eggs.

2 MAMMALS All wild species are covered, including whales, dolphins and other marine mammals. Tracks are shown where appropriate.



3 REPTILES Coverage includes close-ups that reveal the often subtle color and pattern differences between species. Easily tamed species are noted.



4 AMPHIBIANS are represented by more than 100 species of frogs, toads and salamanders, with details on habits, life-cycles and voices.

5 MOLLUSKS All major groups of commonly found shells are colorfully represented, as well as squids, octopi and other shell-less species.

7 OTHER MARINE INVERTEBRATES include corals, sponges, starfish, crustaceans, jellyfish and many equally fascinating creatures.

6 FISHES All fresh- and saltwater food and game fishes are included, as well as other often-encountered species.

An Alternate Selection of the Literary Guild and the Library of Science, A Main Selection of the Natural Science Book Club, the Birding Book Society, and the Outdoor Life Book Club.

Teilhard became convinced that Piltdown was two creatures when he came to know Davidson Black and Franz Weidenreich in China, and that this discovery was such a "personal blow" for Teilhard that he loathed the subject of Piltdown ever after. But von Koenigswald's chronology is wrong. Teilhard's 1920 article—published long before he went to China—correctly chose the two-creature hypothesis for the skull and jaw. Of all Piltdown's early discoverers and champions, Teilhard had the least cause for embarrassment. He had never published an enthusiastic comment on the discovery. His only article on Piltdown called it as right as he could without crying fraud (two creatures, mixed together in the same deposit), and he had shut up thereafter.

Washburn apparently prefers the "official" story of Dawson acting alone, my own preference until I found the Oakley letters. Von Koenigswald's attitude is curious. After castigating me in no uncertain terms for my unscholarly willingness to point the finger of blame, he states with more definiteness than I ever imposed upon Teilhard that "the person responsible for the fraud was Professor W. J. Sollas." He then falsely states that I overlooked this proposal and asserts that, had I known of it, my "concoctions would never have been printed." But if Professor von Koenigswald would care to read the first column of my article, he will see that I mentioned the Sollas accusation and dismissed it. True, I did not discuss the point in depth, but my article was long enough and I had already presented a lengthy rebuttal of the Sollas case in my first Piltdown piece (*Natural History*, March 1979).

The Sollas case seems so farfetched to me (and to all others I have contacted who know the details of Piltdown intimately) that I still cannot understand why it attracted so much publicity. It was this incredulity that inspired my first piece. (That article, by the way, did not focus on *whodunit*, but on the subject correctly identified by Washburn as far more important for the history of science in general—why did major scientists ever accept Piltdown.) The Sollas case rests entirely on a tape recording made by J. A. Douglas, the 93-year-old emeritus professor of geology at Oxford (Sollas's successor), just before he died. The professor's case, based on some fifty-year-old suspicions, is idiosyncratic and conjectural. He simply states that Sollas hated Smith Woodward, that Sollas had potential access to bones for the forgery (as did anyone in a major museum and many amateur collectors as well), and that he remembers the arrival of a package of potassium bichromate addressed to Sollas. (This chemical stained the Piltdown bones, but it also had a variety of legitimate uses.) No evidence links Sollas with Dawson or ever places him at Piltdown.

Dodson offers the entire smorgasbord of other possibilities. He also mentions Sollas and the even more unlikely prospect of Grafton Elliot Smith. Ronald Millar's implication of Smith died a quick and well-deserved death after he published it in 1972. Millar grasped at some straws, established no link to Dawson and no evidence for any tie with the Piltdown site. In fact, Smith was the most severely duped and used of all Piltdown's champions. He staked his career on the belief that increase in brain size was a trigger for all subsequent human evolution. A human skull attached to an ape's jaw might have been designed to feed this prejudice, and Smith fell for Piltdown with an ardor unmatched by any other supporter. And lest anyone imagine that he constructed Piltdown to advance his *idée fixe,* Smith was far too subtle a scientist to imagine that he could get away with such a hoax permanently (since any future discovery would destroy him and his thesis forever) and too excellent an anatomist to do such a poor job of forging.

Dodson, to my amazement, even dredges up Butterfield, although my surprise is lessened by Dodson's admission that he hasn't read the accusation itself. The Butterfield story even makes the Sollas case rich by comparison. It is based on nothing more, ironically, than a letter from Teilhard to his parents stating that Butterfield was angry with Dawson for not donating some fossil specimens to his local museum.

Anyone with even the slightest peripheral relationship to Piltdown has been accused by someone or other. People half a world away, people who never knew Dawson, people who never visited Piltdown have been implicated. Teilhard has largely escaped public scrutiny (although he provoked a great deal of private suspicion). But Teilhard was at the site continually. He met Dawson three years before Smith Woodward even heard of the finds. Teilhard and Dawson became friends and prospected together extensively. Why not look close to home, when such a good case is at hand.

In short, none of the three commentators has raised a single substantive point against my thesis. To my knowledge, only one substantive claim has been advanced by anyone, either in public or in private. One of Teilhard's biographers, Mary Lukas, has charged that Oakley and I and all who ever read the Oakley letters have uniformly misinterpreted them. She claims that Teilhard was referring, not to the second Piltdown site—the one Dawson uncovered in 1915—but to a second pit at the first site. But this cannot be because each of three times that Teilhard mentions this second find, he refers to it explicitly as the place "where the two small fragments of skull and the isolated molar were supposedly found in the rubble." Only one place yielded two skull fragments and a molar: the second site, "discovered" by Dawson in 1915.

One final comment, almost as a point of personal privilege: Both Washburn and von Koenigswald (and others in private) have accused me of a particularly distasteful form of nastiness in attempting to tarnish the reputation of a man no longer able to defend himself. Washburn talks of the "reputation of a person long dead who cannot set the record straight." Von Koenigswald, in his covering letter, speaks of my "cheap insult of a dead hero who cannot defend himself." Now, had I suspected Teilhard when he still lived and purposely kept silent awaiting his death, the charges would be well founded. But I was thirteen years old when Teilhard died, and I had never heard of him. The subject of history might as well fold up its tent if it must follow the old motto for eulogies—*de mortuis nihil nisi bonum* ("say only good of the dead"). Most people who ever lived are dead.

The operative sentence of my original article follows, and I see no reason to alter it: "My case is, to be sure, circumstantial (as is the case against Dawson or anyone else), but I believe that the burden of proof must now rest with those who would hold Father Teilhard blameless."

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

hexa·photo·cybernetic
The Possibilities are Endless.

Shutter-Priority: 1000 S 6

Six-mode exposure control. System versatility. Newer electronics for wider applications.

The Canon A-1 is one of the world's most advanced automatic SLR cameras. Combining the finest in optical and mechanical engineering with the most sophisticated electronics, it's technology applied to give you the ultimate in creative control. At the touch of a button.

Depending on your subject, you can choose from six independent exposure modes to achieve the results you want:

1 Shutter-Priority: You select the shutter speed, to freeze the action and prevent camera shake or create an intentional blur. The A-1 automatically selects the appropriate lens opening.

2 Aperture-Priority: Control the area in focus by selecting the lens opening for the effect you want. The A-1 matches with the right speed.

3 Programmed: When you need to shoot fast, just focus. The A-1 will select *both speed and aperture* for great results.

4 Stopped-Down: For extreme close-up or specialized photography, a bellows, a microscope or almost anything can be attached to the A-1. It's still automatic.

5 Flash: Totally automatic flash photography, of course, with a wide variety of Canon Speedlites to choose from.

6 Manual: Yes. For those times when you absolutely want to do it all yourself. To experiment. To explore the possibilities.

There are over forty fine Canon lenses ranging from Fish Eye to Super Telephoto, plus accessories to meet every need. If you can't photograph your subject with a Canon A-1, it probably can't be photographed.

From the sophistication of its LED viewfinder display, to a ruggedness that allows up to five-frame-per-second motor drive, the Canon A-1 represents an incredible technology. At a price that makes owning one a definite possibility.
